The institutions of the metropolis for the purposes of the professional education of legal and medical men having been already noticed, it seems proper to advert to those establishments which are designed to promote and diffuse knowledge in general, whether scientific, historical, or classical.

The first of these is the *Royal Society*, founded in the reign of Charles II., now holding its meetings in apartments provided by the crown for that purpose in Somerset House. Its labours and its merits are so well known, that any description or encomium here would be superfluous. It consists of a president and a council, composed, with the vice-presidents, of twenty members, and a numerous body of fellows chosen by ballot. It has a secretary, an assistant secretary, and librarian, and holds weekly meetings on Thursday evening, and one annual meeting on the 30th of November, when the council and officers are chosen.

The *Royal Society of Antiquaries* was founded in 1751, and is also provided with apartments by the public in Somerset House. It is managed by a council of twenty-two members, chosen annually on the 23d of April, and has weekly meetings on the Thursday evenings. Its researches into the antiquities of this kingdom, and of other countries, ave been diligent, and have thrown great light upon many istorical subjects and events.

The *Royal Society of Literature* is of recent origin, aving been founded in 1825. It has published two vo- umes of its proceedings, of great curiosity, and has contributed to the inquiry respecting the Egyptian hieroglyphics, by printing several fasciculi of such of them as seem in the best preservation. It has a president, ten vice-pre- dents, and a council, annually chosen of fifteen members, including the English and foreign secretary, and the trea- urer. Its weekly meetings are on the Thursday morning, at the house which it has built in St Martin's Place, Charing ross.

The *Royal Institution* in Albemarle Street, was founded in 1800, chiefly by the exertions of Count Rumford. It has a good chemical apparatus, which was long employed in the best manner by the late Sir Humphry Davy, and, after his connection with it ceased, lectures continued to be delivered, both on subjects of science and taste, which have had much influence on the promotion of knowledge. It has a tolerable library, and the current periodical literature is collected for the use of members. The lectures are announced in the journals.

The *London Institution*, in Finsbury Circus, is an establishment of the same kind as that in Albemarle Street. It is a handsome erection, and has a most valuable library, well arranged, and lectures are delivered on scientific subjects.

The *Linnæan Society* was founded in 1802, in Soho Square, it holds its meetings on alternate Thursdays, in the evening, and has been successful in extending the knowledge of botany, both as regards foreign and British plants.

The *Horticultural Society*, whose objects are pointed out by its name, was founded in 1808, and has a suite of apartments in Regent Street, where, on alternate Tuesdays, in the season, displays are made of improved specimens of fruits, flowers, and other products of the garden.

The *Zoological Society* was first established in 1829, and in the few years that have passed, has met with unexampled success and approbation. Its house is in Bruton Street, where a large collection of stuffed animals may be seen; but the most attractive part of this institution is its garden in the Regent's Park, to be hereafter noticed.

The *Royal Asiatic Society* was founded in the year 1820, in Grafton Street, and holds its weekly meetings on Saturday, and is occupied with researches into eastern literature.

These societies are here separately classed, because they are chartered bodies; but there are others without charters which are not less useful or respectable, and equally deserving of notice.

The *Society for the Encouragement of Arts, Manufactures, and Commerce*, was first established in the year 1754, and has beneficially applied itself to the purpose which its name announces. It meets in John Street, Adelphi, but has annual exhibitions, in some larger buildings, of improved mechanism, and of other inventions, and of specimens in the fine arts, where prizes of an appropriate nature are distributed to successful competitors.

The *Russell Institution*, in Great Coram Street; the Western Literary and Scientific Institution in Leicester Square; the city of London Literary and Scientific Institution in Aldersgate Street; the Metropolitan Literary Institution in Chatham Place; the Surrey Institution, in Union Row, Camberwell; the Southwark Literary and Scientific Institution, in Trinity Place, Blackman Street; and the Belgrave Institution, in Sloane Street, have all been established within the last fifteen years. Their objects are the same as those of the Royal and the London Institution, and, as far as their several degrees of pecuniary power extend, they are of use in promoting the spread of knowledge.

The *Society*, properly described by its name as having for its object *the Diffusion of Useful Knowledge*, now forms a prominent part of the means of general instruction. It was first established in 1827, in South Square, Gray's Inn, and its progress has been excessively rapid. Its attention is chiefly directed to publishing, in a form so economical, as to bring them within the reach of a vast number of persons, a great variety of works of such a nature, as must tend to improve the minds of those who are anxious to acquire knowledge. By using good but not high priced paper, by stereotyping, and by printing large editions, they are enabled to furnish their books at very low rates. Their Almanac, their Penny Magazine, their Penny Cyclopædia, and numerous other works, are all well and faithfully executed, and every degree of scrutiny is applied to prevent in them the insertion of whatever may tend to weaken the moral or religious principles of the readers.

Some other societies have been formed on the same, or nearly the same plan; but, though equally commendable in their design and execution, they have not been attended with equal success.

The *Geological Society*, formed in 1826, has been favoured with a suite of apartments by government, in Somerset House, where its valuable collection of fossil and mineral specimens is rapidly increasing. It meets on the first and third Fridays in each month, when communications are made which must tend to increase the knowledge of this branch of science.

The *Astronomical Society*, though not of more than twelve years' existence, has acquired and maintained the highest reputation by its publications. It is composed of the most eminent astronomers of this kingdom, and holds a constant communication with those of other countries. It holds monthly meetings on the second Friday of each month, but its principal labours are performed in the observatories of the several members, of which several have been erected in different parts of the kingdom, chiefly in consequence of the impulse given by the society.

The Fine Arts have also societies established for their promotion, which may be mentioned here. The *Royal Academy of Arts* was established by royal charter in 1768, and has apartments at Somerset House, where they have a good collection of paintings, casts, and statuary, and where, under their direction, an annual exhibition is made of the productions of the pencil and the chisel of British artists.

The *British Institution*, in Pall Mall, is an association of amateurs, who obtain the best pictures from their owners, and produce them annually in an exhibition at their house. It was founded in the year 1805. There is besides the Society of Painters in Water Colours, who annually exhibit the productions of its members and others. The powers of the art, in this branch, are very great, and have rapidly increased since the establishment of this society in the year 1804.

The societies for the cultivation of music are all of recent formation. Those which may be distinguished as public institutions are the Royal Academy of Music in Tenterden Street, founded in 1822; the Royal Harmonic Institution, in Regent Street; the Philharmonic and the Metropolitan Cambrian Institution. This delightful art is taught in both instrumental and vocal branches, by numerous private professors, and is displayed at the numerous private concerts annually given by eminent performers, in the theatres, and the various assemblages where dancing is combined with it.

Colleges and Schools.

Amongst the most prominent institutions for general instruction, the *London University* deserves the first notice. It was commenced by voluntary contributions, begun at a public meeting in July 1825, and commenced some slight operations in the February following, and the first stone of the building was laid on the 30th of April 1827. It was designed upon a plan so extensive, that the pecuniary means to execute it were found insufficient, and the centre only has been finished. It is a beautiful and classical edifice, and, in its present state, is sufficiently ample for the number of students. The whole is well arranged with lecture rooms, apartments for the apparatus of natural philosophy, a spacious library, and an anatomical theatre. It receives pupils in law, in the various branches of medical study, in the general sciences, in classics, and in modern languages. The professors have usually been men eminent in the respective branches they undertake to teach, but the frequent change in them must have been somewhat disadvantageous.

The number of pupils in 1835 was as follows:—In the medical school 394, of whom sixteen attended to veterinary medicine alone, and of the remainder 132 attended the practice of the hospital. The students in the Faculty of Arts were 141, of whom fifteen attended solely to law. Twenty-five of them attended law and other subjects, and seven of them attended political economy. The numbers in the junior school were 375, thus making a total of 901.

King's College was founded somewhat later than the London University. It has been built by voluntary subscriptions, on a vacant piece of ground on the east side of Somerset House, and has been erected so as, in harmony with that building, to form one of the wings of its front towards the river Thames. It was opened on the 8th of October 1831. The college is patronized by the dignitaries of the church and the more zealous of its lay members, and instruction in the Christian religion, according to the forms and faith of the establishment, forms part of the course of education. In the chapel daily religious worship is performed. In these two respects it differs from the London University. The other subjects of education for which it provides are attended to by professors of great merit, and in this respect it differs but little from the rival institution. The college has attached to it a preparatory school, where the first elements of classical literature are well impressed on the pupils, and where the modern languages are taught.

The number of pupils, in the beginning of 1835, was as follows:—

Regular students for the prescribed course, .	133	
Occasional students in various departments of science and literature, ...	104	
		237
Medical department:—		
Students for the whole course, ...	42	
Occasional students in various branches, . .	175	
		217
Junior branch, for the general course of instruction,		461
Total, . .		915

Within the metropolis are several schools for classical literature of the highest kind, besides those of the Charterhouse, and of Christ's Hospital, for a select number of pupils, which have already been noticed. The most celebrated is St Paul's School, founded by Dean Collet, in 1509. It is at the eastern end of St Paul's Churchyard, and has been rebuilt on the same site since the year 1822. It is an elegant building, with a magnificent portico supported by six columns. It was originally destined to educate 150 boys gratis, but has now more than double that number. The masters are excellent. The school consists of eight forms; in the first the rudiments are taught, and the pupils are advanced to the eighth, from which, with a competent portion of Latin, Greek, and Hebrew, they are removed to one of the universities, where they have the benefit of good exhibitions. The Mercers' Company are the trustees of the institution.

Merchant Tailors' School, in Suffolk Lane, Canon Street, was founded by that company in the year 1561. The building was destroyed by the great fire of 1666, and the present house erected on the same spot. It is very spacious, and supported on the east by stone pillars, forming a cloister, within which are apartments for the ushers. Adjoining the school are the library and chapel, and contiguous is a house for the head master.

In the school about 300 boys are educated, of whom 100 are taught gratis, 50 at 2s. 6d. per quarter, and 50 at 5s. Annual examinations are held, and public exercises performed by the scholars, of whom several are sent annually to St John's College, Oxford, which was principally founded for the use of this school, and where there are no less than forty-six fellowships for those educated in it.

Besides these classical schools of ancient foundation, many valuable institutions have been recently formed by a kind of joint-stock proprietors, which afford excellent education. They are in connexion with King's College, and have similar regulations and methods of teaching with that institution. They are built in good taste, and capable of receiving about 300 boys, and of qualifying them for admission to the universities. Already one has been opened at Pimlico, one at Kensington, one at Islington, one at Hackney; and in several other parts of London they are either built or building. Those boys sent by proprietors are taken at a little lower rate than the others, but the highest charge is moderate.

It is impossible to calculate the number of day and of boarding-schools for both sexes in and around the metropolis. They are of all degrees of utility, and of all classes, as regards the expense of them.

Attention to the education of the poor has vastly increased of late years. Half a century ago there were in every part of the city what were called ward-schools, in which a number of both sexes were taught reading and writing, and the catechism, and uniformly clothed; and in each of the out-parishes the same system was followed. These, to the number of eight or nine thousand, were accustomed to attend divine service on a fixed day at St Paul's, where temporary seats under the dome were prepared for them, and they presented a most striking and even delightful exhibition. Of late years other schools upon what is called the national plan have been framed and increased. Infant and day schools have also been established, and instruct great numbers.

By a report of a committee of the House of Commons, made in 1833, the following is the result of the inquiry instituted as regards purely charity schools of all kinds:—

1st, Infant schools, . .	109		
Number of males in them, .		3,065	
... ... females		2,441	
... aged from two to seven years, but the sex not specified, ...		3,226	
			8,732
2d, Daily schools, . . .	2,152		
Number of males, . .		49,991	
... ... females, . .		34,446	
Sex not specified, . .		8,051	
			92,488
3d, Sunday schools, . .	329		
Number of males, . .		23,440	
... ... females, . .		23,225	
Sex not specified, . .		5,456	
			52,121
Schools, .	2590	Pupils	153,341

Schools established by Dissenters,—

	Schools.	Scholars.
Infant schools, . . .	7	577
Daily schools, . . .	103	9,170
Sunday schools, . . .	150	27,689
	260	37,436

The above are returns from the county of Middlesex, including the city and Westminster; and if the inhabitants of the county beyond the limits of the metropolis be taken as equal to those in the Southwark part of the metropolis, the result will be the same.

Places of amusement.

In the amusements of the metropolis the attention is first of all attracted to the theatres. Considering the number of inhabitants and their aggregate wealth, London has fewer of such houses than most of the other capitals of Europe. The most fashionable and splendid is the *Opera House*, where the music and the dancing highly delight the visitors. It was burned down in 1790, and has since been rebuilt at an enormous expense, from a design of Nash. The interior is arranged with a total disregard of cost. It is nearly the largest theatre in Europe. The stage is sixty feet long, and eighty broad, and the distance between the opposite boxes is forty-six feet. Each box is inclosed with curtains, and those who occupy them sit in chairs. These boxes are either private property or hired for the season. The pit and gallery are open to those who chuse to pay the price. The whole is capable of accommodating 2500 spectators, and those who frequent it are either persons of the highest rank or amateurs, or those who are desirous of being thought to belong to one or other of these classes. The prices of admission are high, but do not equal the expense of the establishment, which is involved in debt, and also frequently embroiled with proceedings in the Court of Chancery.

Drury Lane Theatre, in Bridge Street, enjoys, with the theatre in Covent Garden, a kind of monopoly, by patent, as far as regards the mere exhibition of tragedy and comedy. It has been burned down, but was replaced in 1811 by the present large edifice. It is simple, and of the Doric order, having in front a handsome portico, surmounted by a statue of Shakspeare, added in 1820. The grand entrance leads through a spacious hall, supported by five Doric columns, to an elegant rotunda, whence staircases ascend to the boxes. The interior of the house presents about three quarters of a circle from the stage, and has a splendid though not a gaudy appearance. It is illuminated by an elegant gas chandelier, which hangs over the centre of the pit. The stage at the opening of the curtain is 43 feet wide and 38 high. The diameter of the pit is 53 feet, and the height of the house from the pit floor to the ceiling is 50 feet. It is calculated that 3600 persons may be conveniently seated, one-half of which number must be in the boxes. During Lent performances of sacred music are given instead of regular dramas.

Covent Garden Theatre has its principal front in Bow Street, and much of the rest of the building is hid by houses. It was destroyed by fire in 1808, after which the present edifice was erected on an extensive scale. It is nearly of a square form, and the design was taken from the Temple of Diana in the Acropolis of Athens. The front is ornamented with statues representing comedy and tragedy, and *basso-relievos* descriptive of the ancient and modern drama. The interior is elegant, having at the entrance an Ionic staircase, between the columns of which are suspended Grecian lamps. The stage is very spacious, and there are three rows of boxes, an extensive pit, and two galleries, which are calculated to seat 3000 spectators; it is throughout lighted by gas. A superb chandelier over the centre of the pit produces a fine effect. When the house is crowded the admission money received at the doors amounts to about L.900.

From the complicated nature of the property, both these great theatres, like the Opera House, have been the subject of frequent litigation, and heavy charges have on that account been incurred. The Court of Chancery has seldom been free from dramatic suits. The taste for dramatic performances in this country appears of late to have changed much, and owing to the size of the houses, which are too large for the human voice to be distinctly heard, the pieces represented depend more upon splendid exhibitions that strike the eye than upon the elegant language of the authors of dramatic works. The expense of these kinds of exhibitions, and the falling off of spectators, have very much embarrassed the affairs of these great concerns.

Whilst the two great theatres are closed, that in the Haymarket is allowed to be opened. It was once occupied by the celebrated Foote. The present house, on the same site, was rebuilt in 1821, from the designs of Mr Nash. The front is ornamented with a lofty portico, supported by six columns of the Corinthian order, over which are nine circular windows, richly sculptured. It is much smaller than the two regular theatres, but has two ranges of boxes, with a pit and gallery. The prices of admission are lower than at the other houses. Sometimes a company of French actors have performed in it.

Besides these, which may be called the houses of the regular drama, several theatres have been opened which require to be briefly noticed.

The *English Opera House, or Lyceum*, in the Strand, is newly rebuilt, after being destroyed by a fire in 1830. As its name denotes, the pieces represented are in a great measure musical. In the interior, it is 40 feet in diameter, and 37 feet in height, with a handsome saloon 63 feet by 24.

The *Royal Circus*, or *Surrey Theatre*, in Blackfriars Road, was chiefly destined for exhibitions of horsemanship, but has of late produced ballets, melo-dramas, and similar performances.

The *Royal Victoria Theatre*, in Waterloo Bridge Road, built in 1818, is well calculated for dramatic representations, but the performers are not of the highest class. It is sometimes called the Coburg Theatre.

Saddler's Wells, in St John's Street Road, is an old establishment, with the new river sometimes turned into it, by which it is enabled to represent aquatic scenes, such as Naumachia, Fingal's Cave, and others.

At the *Royal Amphitheatre*, or *Astley's*, near Westminster Bridge, are exhibited feats of horsemanship, rope-dancing, and other amusements; it is much frequented by children during the school vacations.

The *Royal Adelphi Theatre* in the Strand, sometimes distinguished as the *Sans Pareil*, is now open for entertainments of the comic kind, in which the powers of Mathews used to be much admired.

The *Olympic Theatre* in Wych Street was used for equestrian performances, but, under the management of Madame Vestris, has become a place for exhibiting vaudevilles and dancing.

The *Royal Fitzroy Theatre* in Tottenham Court Street exhibits performances of farces, burlettas, and pantomimes. It was formerly called the Regency Theatre.

According to some newly-contrived plans, theatres of a still lower description are kept open. These are the Royal Clarence, near Battle Bridge; the Queen's Theatre, Windmill Street, Haymarket; Dibdin's Sans Souci Theatre, London Bridge Theatre, and Ducrow's Olympic Circle in Whitechapel.

In the summer months, the gardens of Vauxhall, on the Surrey side of the new bridge of that name, are an inviting place of amusement. They have been a place of resort for more than a century, and during that whole period have been constantly improving in decoration, as well as advancing in the price paid for admission. These gardens are extensive, and, when lighted, have a beautiful appearance, from the variegated lamps in the several walks, from different portions of light distributed in the walks, and from the numerous embellishments. In the centre is an orchestra, and opposite to it an elegant pavilion for large parties, whilst in other places are boxes of various sizes, suited to large or small parties, in which refreshments are served. Many of these are adorned with paintings. In fine weather the music is performed in the orchestra, but when it is damp the band is assembled in the rotunda, which is a fine apartment, seventy feet in diameter, adorned with some fine historical paintings upon the walls. Parties are formed for dancing in many parts of the premises, and in the few weeks of very warm weather it is a delightful place of recreation. The fire-works are magnificent, and there are many transparencies exhibited. Few objects in London have so striking an effect on foreigners as the sight of these gardens, and hence almost every large city on the continent has in its environs an establishment of a similar kind, all retaining the name which it bears in the country whence the idea was conveyed to them.

Clubs.

In so vast an assemblage of persons as London presents, where the incomes, the tastes, the education, and the manners are so various, it is difficult to describe the several sources of amusement that occupy their spare time. Public exhibitions do not seem so congenial to our habits as to the inhabitants of more southern climates; and other sources of relaxation require to be provided. Amongst the male portion of the higher classes, the club-houses are a refuge from ennui; and they have greatly increased of late years, both in numbers and in elegance of building, decoration, and furniture. At all of them newspapers, periodical publications, and the current new works are provided; dinners, breakfasts, and refreshments are prepared; and in most of them, in moderation, but in others to a disgraceful extent, the practice of play is introduced. In these clubs congenial society is to be found, for though some of them are more open than others, yet many are restricted to particular walks of life. Thus the United Service, the Naval, the Military, the University, and others are composed of one description; but as many members of them are also members of other clubs, such as the Athenæum, the Travellers, the Alfred, the Union, and others, a sufficient variety is found to enable them to keep free from what may be denominated clanship.

As there are already more than twenty-five of these societies, varying in their regulations in the sum paid at admission, and in the annual subscriptions, it would be useless, as well as tiresome, to describe them. The number of members in each club varies very much, a few having but 400, and still fewer 1500. The subscribers to the whole amount at present to about 18,000; but as some subscribe to more than one, and a few to three or four, it may fairly be estimated, that the number of gentlemen, of some consideration and wealth, who find amusement in these elegant houses, cannot be less than 12,000. The sums annually expended in these establishments, when the cost of their erection is included, has been calculated to amount to more than L.160,000 annually.

Coffee-houses.

The coffeehouses, which formerly abounded, and then formed a favourite lounge for many persons, have much decreased with the growth of clubs, which have a less promiscuous society, as none who has not some tolerable pretensions can easily become a member. These meetings form a medium between domestic circles and public assemblies, and are in tolerable harmony with the character and disposition which prevail in what is usually termed good English society.

Bazars.

Another source of amusement has been of late introduced, but rather more appropriate to the ladies than to the gentlemen. These are the bazars, consisting of shops, or rather stalls, for the sale of elegant light fancy articles, either of dress or of domestic ornament, but comprehending a great variety of goods, and, what is of importance, mostly served by respectable females. Some of these display uncommon elegance in their fittings up. The most remarkable of the number are the Soho Bazar, in the square of that name; the Queen's Bazar, in Oxford Street; and the

Pantechnicon, in Belgrave Place, which have been the longest open. These have, however, been vastly excelled by a new one in St James's Street, opened in 1832. It consists of two spacious halls on the ground and first floor, which communicate by a magnificent staircase, decorated with mirrors of a large size. But another in the building, known by the name of the Pantheon in Oxford Street, opened in 1834, is thought to excel the St James's Bazar. The form of the interior, the adjoining garden, and the decorations, give it a peculiar character, and excite great admiration.

To these amusements must be added, the indulgence of agreeable walks in St James's and the Green Parks, whose beauties have been much improved within the last few years, the promenades in Hyde Park or the Regent Park, and the delightful mixture of wood and water to be enjoyed in Kensington Gardens.

In a city of such vast extent as the metropolis, there are many objects worthy of consideration, which cannot well be grouped under any specific class; and though, to a certain extent, it has been attempted in this article, it becomes convenient to take a survey by making a kind of tour of the different parts comprising the whole. In doing this it seems desirable to begin with the city, and proceed round it from the east, to the north and the west, and end with the south or Surrey side.

The *Guildhall* of the city of London, being the termination of King Street, proceeding from Cheapside, is an ancient building of the beginning of the fifteenth century. Before its erection the court-hall of the city was in Aldermanbury, whence it was removed in 1411 to the present edifice. It has a Gothic front, recently put in a good state of repair. The great hall is 153 feet in length, 48 in breadth, and 55 in height, and from its capaciousness, is capable of containing seven or eight thousand persons. At the east end is a raised platform called the hustings, from which, at elections, or other public occasions, the speakers address the audience, but can, with difficulty, make themselves heard by those at the lower end. It is also used as a dining apartment on the festival usually called Lord Mayor's Day, held in November. Over one of the windows are two colossal figures, commonly named Gog and Magog, which are supposed to represent a Saxon and an ancient Briton. This apartment is ornamented by some sculpture, in honour of Lord Chatham, by Bacon; in honour of his son William Pitt, by Bubb; and of Lord Nelson, by Smith. There is also a statue to Alderman Beckford by Moore, with a speech that never was spoken, but written by Horne Tooke. Over the entrance is the orchestra, and opposite to it the passage leading to the chamber in which the Common Council assemble, and other rooms, which are occupied by the judges of the Court of King's Bench, Common Pleas, and Exchequer for the trial of city causes. The Common Council Room is ornamented with some good pictures and busts of Lord Nelson, the Duke of Wellington, and Granville Sharp. The Chamberlain's office is in one part of the building, and there is within it a library, with a good collection of books and papers belonging to the city, and adjoining to it is a museum. Near to it is an apartment for the sitting alderman; and on the side is Blackwall Hall, which is now used as the Court of Bankruptcy.

The *Mansion-House* is the residence of the Lord Mayor of London during his year of office. It is a large stone building, erected upon the site of a market called Stocks, between the year 1739 and 1753. No public building has been the subject of more severe architectural criticism than this. It is, however, in spite of a heavy structure over the pediment, a magnificent pile, and is also seen to great disadvantage by its confined situation; but this evil is now remedied by the removal of some of the houses that hid the view of it, and by the opening of a more spacious way to it direct from the New London Bridge. The front has a wide and lofty portico, composed of six fluted columns of the Corinthian order, with two pilasters on each side. Beneath this portico, a flight of steps on both sides leads to the principal entrance. On the left of the entrance-hall is the justice-room, a kind of court of justice, in which the Lord Mayor sits daily in his magisterial capacity. On the principal floor is a magnificent hall, described as the Egyptian Hall, adjoining to which is an elegant and spacious drawing-room. The Egyptian Hall is used for dinner parties, of a more select kind than is usually collected upon the Lord Mayor's Day at the Guildhall. Easter Monday is the chief festival, when after the dinner a ball is given, in a suitable apartment on the next story above. There are in it good family apartments, and suitable apartments for cooking and for servants.

Merchant Tailors' Hall, belongs to one of the richest of the guilds or companies of the city of London. It stands in Threadneedle Street, on the south side. The hall is one of the largest and best proportioned rooms in the city, and it is chiefly remarkable for the great number of men, the most eminent for rank and talent, who have been members of the company, and whose portraits are here to be seen. This company was founded in the reign of Henry VII., in the year 1480, and is called in the charter the art and mystery of the fraternity of John the Baptist. There have at different times been admitted into it seven kings, one queen, seventeen princes and dukes, two duchesses, one archbishop, thirty-one earls, five countesses, one viscount, twenty-four bishops, sixty-six barons, seven abbots, seven priors, and an innumerable list of esquires. In the present day some of our most illustrious men have been admitted to the fellowship; and the annual festivals are distinguished by the rank, talent, and virtues of those who join in them. The company possesses large estates, the income of which is chiefly devoted to benevolent purposes. They support an hospital for their decayed members, and are the patrons of a school, in which the pupils have been regularly imbued with a degree of classical knowledge. The school is in Suffolk Lane, Cannon Street. It is a fine building, forming a kind of cloister, in which are apartments for the master and three ushers. There are in it about 300 boys, of whom 100 are taught gratis, and 50 at ten shillings a-year. They have valuable exhibitions, and numerous fellowships; at St John's College, Cambridge, numbers are annually elected, according to the proficiency which they discover at the general examination.

Many of the other guilds of the city, of which there are no less than ninety-one, called companies, have halls, a few of them very fine buildings, and most of them sufficiently large; but many of the smaller companies being destitute of such accommodations, hold their meetings in taverns.

The goldsmiths existed as early as the year 1180, and were long the chief bankers of the metropolis. They have now the assaying of all articles made of gold and silver. Their hall has been recently rebuilt upon the site of the former, in Foster Lane. It is an edifice of noble proportions, the centre of which is composed of six Corinthian columns, supporting an entablature surmounted by a rich cornice. The five centre windows have balconies, and over them are the sculptured arms of the company. The furniture and decorations of this new building excite the highest admiration.

The hall of the drapers, in Throgmorton Street, is a large square building, on the site of the residence of Cromwell Earl of Essex. It has handsome apartments, a good garden, and is adorned with a fine portrait of Lord Nelson, by Beechey, and some others. This company has some large estates in Ireland.

Stationers' Hall is a large but plain building, in a court out of Ludgate Hill, formerly inhabited by a succession of noblemen of the first rank, from the reign of Edward II. to that of Elizabeth, when an Earl of Abergavenny sold it to the company, which then, as now, was a rich trading body. It was destroyed by the fire of 1666, when the loss in books and other property was estimated at L.200,000. It had long the monopoly of publishing almanacs, and though it has lost the exclusive privilege, continues to print large editions under the name of Francis Moore, by which and other operations, the members are enabled to divide some profit amongst themselves.

Mercers' Hall, in Cheapside, was originally the hospital of St Thomas, having been the birth-place of the venerated Saint Thomas-a-Becket. The present building was erected after the great fire. The front is adorned with figures of Faith, Hope, and Charity, and it contains some very fine apartments. It is a rich corporation, with considerable patronage; and in the list of its members more than sixty have been Lord Mayors, amongst the rest Whittington, Sir Richard Gresham, and Sir Thomas Gresham.

The *Fishmongers* are a rich company, having some large estates in the north of Ireland. Their hall being removed for the purpose of constructing New London Bridge, a new and elegant one has been erected at the foot of that fine pile. It is executed with much taste from the design of Mr Roberts, presenting an imposing front towards the river, and another towards the street. It has a granite basement and the superstructure is of Portland stone.

Grocers' Hall is a handsome building, but hidden, from standing in a small court. It has a spacious public apartment, in which are portraits of Lord Chatham, and of his son William Pitt, who were members of the company. Other halls deserve mention and inspection, but our limits forbid even a short description of them. The best are, Ironmongers' Hall, in Fenchurch Street; Barbers' Hall, in Monkwell Street; Salters' Hall, in a court of Cannon Street; Skinners' Hall, on Dowgate Hill; Saddlers' Hall, in Cheapside; Coachmakers' Hall, in Noble Street; Vintners' Hall, in Thames Street; and Painters' Hall, in Trinity Lane.

That elegant Doric column called the *Monument*, on Fish Street Hill, is a splendid specimen of the taste and genius of its architect Sir Christopher Wren. It was constructed to commemorate the great fire of London in 1666, which destroyed the chief part of the city, and broke out in Pudding Lane, near to the pillar. It is a fluted column, rising from the ground to the height of 202 feet. It stands on a square pedestal of 40 feet, and the diameter of the shaft is 15 feet. There is a winding marble staircase within it, which gives access to a gallery with an iron balcony, from which is a fine view of the city and the suburbs. The top of the column terminates in a large blazing urn of brass gilded. This work was commenced in 1671, and finished in seven years, at the expense of L.14,500. It is built wholly of Portland stone, of which it is said 28,500 feet were employed. On the northern face of the pedestal is an inscription in Latin, narrating the circumstances of the fire, and stating, that the destruction occasioned by it was 89 churches, the guildhall, city-gates, many public structures, hospitals, schools, libraries, a great number of stately edifices, and 13,200 dwelling-houses, and that the surface thereby covered with ruins and ashes amounted to 436 acres. The inscription on the northern side is designed to commemorate the merits of King Charles II., in assisting to repair the evil created by the fire, and to raise the city again to more than its former splendour. It states that a tax on coals was imposed to pay the expenses, and that, in three years, that was finished which was supposed to require an age. On the eastern side the inscription merely recites the date of the commencement of the column, its progress, and the date of its completion. The western front has an emblematic carving of the tragical scenes which occurred at the fire, which was ably executed by Cibber, the father of the poet and player of that name. The whole building has been repaired of late years; and the inscription on the base, which Pope described as a lie, attributing the fire to the Roman Catholics, was very properly removed in the year 1830.

Sion College, in London Wall, was originally a nunnery attached to the church of St Aphage, Cripplegate; but its resources having failed, it was at length granted to the master of the Jewel Office, who held it till it was destroyed by the great fire; but a fund for its support having been established by Dr White, in 1623, it was again rebuilt, and a society incorporated, having the supervision of the almshouse, in which ten men and as many women are provided for. In a spacious hall, in which meetings of the London clergy are held, is a large and valuable collection of books, to which access is given with great readiness. The institution has been enriched by donations at various times. The library contains many portraits of eminent divines who have been members of the college, amongst whom are those of Archbishops Secker and Tennison, and Bishops Gibson, Compton, Terrick, and Sherlock. A benevolent society has been formed here for the relief of indigent widows and families of the clergy of London and its vicinity.

In proceeding upon a tour from the city, we shall take the course which has been pointed out by the law, in constituting the new boroughs around the metropolis, and thus arrive at the Tower Hamlets. In this part, the most prominent objects have already been noticed, being the Docks, the Mint, and the Trinity House. The dwellings in this borough are mostly occupied by the inferior classes of tradesmen, or by handicraftsmen, or by day-labourers; but there is one object, the Tower of London, whose historical relations entitle it to a fuller notice.

Tower.

Tower of London. The origin of this building is lost in obscurity. It is known, by an examination of boundaries, which took place after the murder of Sir Thomas Overbury, that the walls were built on an ancient foundation, but at what period no evidence could be obtained. The great square tower, called the White Tower, foolishly attributed to Julius Cæsar, was certainly built in 1078, under the direction of a great military architect, Gundulph, bishop of Rochester. Fitzstephen gives it the name of *Arx Palatina*, or the Palatine Tower, and states, most romantically, that the mortar of the foundation was tempered with the blood of beasts. The commander had the title of Palatine bestowed upon him, as was the custom in that age. Within this tower is a very ancient chapel, said by Stowe to be coeval with the building, having a long and dark flight of steps ascending to it. It was used for the devotions of the kings and queens who were residents in the building. In the year 1092, a violent tempest caused much injury to the Tower, which was, however, repaired by William Rufus, and by his successor. The first of those monarchs added another castellated building on the south side, between it and the Thames, which was afterwards called St Thomas's Tower, beneath which was Traitors' Gate, through which state prisoners were led from the river, over which was another gate, with a portcullis, called the Bloody Gate, as few that entered ever left it alive, in the early times of our history, when the name was given to it. The Tower was first encompassed with walls by Longchamp, bishop of Ely, who was chancellor of England in the reign of Richard I. He also constructed the ditch, to which water was introduced from the Thames. Different princes afterwards added other works, and thus, in process of time, enclosed a little more than twelve acres of ground, the circuit on the outside of the ditch of which is 1052 feet.

Finsbury.

The borough of Finsbury, which follows next to that of the Tower Hamlets, is very extensive, and filled with inhabitants of a higher class in general; though in some parts re to be found the worst population of the metropolis. Finsbury Square is a handsome quadrangular range of buildings, surrounding a spacious garden. The houses are lofty, nd well built in the modern style, having been gradually rected for the most part about forty-five years. Near to t is a spacious piece of ground, belonging to a voluntary military society, called the London Artillery Company. There is a good house within the enclosure, where the arms re deposited. In ancient times it was used for archers o practise in shooting arrows against butts. From this place Lunardi sent up the first balloon which had been exhibited in London, in 1783. Near this is the chief cemetery of the Protestant dissenters, known by the name of Bunhill Fields. It was first intended for the burial, at the time of the plague in 1665, of those for whom room could not be made in the churchyards, but afterwards was taken by a Dr Tindal, by whom it was converted to the present purpose. The remains of the most eminent men amongst he dissenting clergy repose in this crowded ground. Of hese, the most remarkable are Neale, the historian; Watts, he poet and divine; Lardner, the author of the Credibility; Dr Guise; Dr Price; Dr Kippis; and Dr Rees. It is attended by a clergyman of the established church, who performs divine service; or the devotional forms of any of the sects may be used by their own ministers. Near to this cemetery are the two chapels of the respective sects of the Methodists, which may be considered as their mother churches. The one, belonging to the Wesleyans, is called the Foundery; the other, belonging to the followers of Whitfield, is called the Tabernacle. They have both respectable and numerous auditors, and the preachers are constantly changed, o as to gratify the taste for variety, which is said to be prevalent among both divisions of that religious sect. In he parish of Clerkenwell, within this borough, is the prison already noticed, for the county of Middlesex; and not ar from it is Hicks's Hall, the court of justice where criminals for light offences are tried. The old hall having become ruinous, was taken down, and the present building erected in 1780. It is of stone, with a rustic basement, over which are four Ionic pillars, and two pilasters, supporting an architrave, frize, and cornice, with a pediment. The interior is divided into the court, the room for magistrates, for the grand jury, and the hall. In one of the rooms s a portrait of the builder of the old hall, Sir Benjamin Hicks. Within the borough of Finsbury are included several objects which have been already taken notice of, such s Luke's Hospital, several churches, and most of the inns f Court, as its limits extend up Holborn, so as to inclose he liberty of the rolls, within which some of them are situated.

The borough of Marylebone next comes under consideration. It consists of the three parishes of Pancras, Marylebone, and Paddington, with (in 1831) 240,294 inhabitants.

The parish of Pancras, now so joined to London as to constitute a part of the metropolis, is very extensive. It is bounded by Islington and Hornsey, and, in one direction, by Finchley, in which one-third of Highgate is comprised. One of its hamlets is Kentish Town, and two modern towns called Somers Town and Camden Town, form a part of it. The whole parish contains an area of 2700 acres. The houses are in general of moderate size, and not much occupied by the fashionable part of society. Within its boundaries is the fine seat of the Earl of Mansfield, Caen or Kenwood. The great lawyer, the first Lord, lived there, having purchased it of Lord Bute. The library in this house s a very fine apartment, ornamented with paintings by Zuchi, and adorned with many valuable busts and portraits. The gardens and woods are very delightful, and have some ne cedars, said to have been planted by the celebrated chief justice. The mother church of Pancras is an ancient building, probably of the fourteenth century; but the adjoining churchyard has long been remarkable for the great number of Roman Catholics that have been interred within it. Most of the tombstones have a cross and the initials R. I. P. (*Requiescat in pace*) are observable on many of them. A reason has been given for this preference, which is, that, at a church in the south of France, dedicated to the same saint, masses were said for the souls of the deceased interred at St Pancras in England. As already noticed, a new and magnificent church has been recently built. A chapel of ease has been erected in Camden Town, within the last few years. At Battlebridge is the Small-Pox Hospital, opened in 1767, and recently used for vaccination, in which more than 100,000 persons have been vaccinated. Part of it is now used as a fever-ward for those who have typhus or scarlet fevers.

Within this part are some fine squares deserving of mention. Brunswick Square is built but on three sides of a quadrangle; the eastern side being occupied by the garden wall of the Foundling Hospital. It consists of about forty comfortable, not very large houses, chiefly occupied by families connected with some branch of the law. It is connected by Bernard's Street with Russell Square, a much larger quadrangle, with an elegant garden in the centre. Many of the houses are very large, and a few of moderate size, but none small. It contains, on the whole, about sixty-eight houses, filled by most respectable families. The following squares are connected with each other by streets of modern built houses, of competent breadth, well furnished with carriage and foot ways, and kept remarkably clean at all times, viz. Mecklenberg Square, with about forty-seven houses; Bedford Square, with fifty-two; Easton Square, with seventy-two; Woburn Square, with forty-two; Tavistock Square, with fifty-five; Torrington Square, with seventy-one; and Burton Crescent, with forty-three; to which may be added Fitzroy Square, which is not far distant, and has forty houses.

This part of the metropolis, which, within the memory of many, was wholly open fields, without a house of any kind, is more remarkable for the respectability and comfort of its inhabitants, than for their splendour, taste, or magnificence. They comprise those who live on incomes already accumulated, or drawn from their professions, chiefly that of the law, or that class of traders who can afford to leave the bustle of the city, for the quiet and greater neatness of such residences. It may be estimated, that the expenditure of the families in these squares, and the streets connecting them, range, according to the size of their dwellings, and the extent of their establishments, from L. 800 to L. 2500 per annum.

There are few public buildings in the part which we are now considering, that deserve especial notice, excepting the churches, to which attention has already been directed, and two objects, which are not indeed within the boundaries of Pancras, but may be appropriately mentioned in this place.

The first is the Foundling Hospital, forming a side of Brunswick Square, opposite to the end of Lamb's Conduit Street. This beneficent institution owes its origin to a Captain Coram, who had been master of a vessel trading to the American colonies, and whose continued exertions for many years at length obtained a charter, when he began the building in 1739. The charity is not strictly for foundlings; nor are they, as in many continental cities, admitted spontaneously. The desertion of the father, and the prudent demeanour of the mother, are the best recommendation; but all applications are carefully examined by the governors, and decided on with the greatest judgment and impartiality. There are about 150 boys and the same number of girls in the house, and some of the younger at nurse, making together about 400. They are taken in during their first year, and are provided with education and all necessaries till their dismission from the establishment. On their departure they are provided with money or necessaries to the value of L. 10; and, in whatever walk of life they enter, they are sure, as long as they conduct themselves well, to find friends to assist them in the institution. Some of the boys are bound apprentices to the sea, and some to trades. The girls are taught needlework, laundry business, and fitted to become servants, and are generally provided with good places at fourteen years of age. There is a handsome chapel, where divine service is performed twice every Sunday, when a collection is made in aid of the funds, which produces liberally. The whole income is about L. 13,000.

British Museum.

The *British Museum* is one of those institutions which reflect honour on the national character. It has been established for nearly a century; the house in which it is deposited having been obtained in 1753. It had belonged to the family of the Dukes of Montague, which name it bore. Sir Robert Cotton had bequeathed to the public his valuable collections earlier, but Sir Hans Sloane, who had made large and valuable collections at the expense of more than L. 50,000, offered them to the public at less than half the money he had expended. The purchase having been completed, the two collections, consisting of various kinds of curiosities in animals, vegetables, fossils, minerals, sculptures, inscriptions, books, manuscripts, and many other objects, were united, and begun to be arranged in the magnificent pile of building still occupied by it, but recently much extended. The building, when first obtained, was situated at the very northern extremity of London, with its back close to fields, which were so solitary, that they were usually selected as the place for deciding what were called affairs of honour. It has now, however, by the extension beyond it of houses of elegant form and of capacious size, become almost a central and very accessible spot.

On entering the gate from Great Russell Street, a spacious quadrangle presents itself to the eye, with an Ionic colonnade on the south side, and the main building 216 feet long and 57 feet high on the north, the two wings being allotted for the residences of the officers. The architect, Peter Puget, a native of Marseilles, was sent over from Paris by Ralph, first Duke of Montague, solely for the purpose of constructing this splendid mansion. Capacious as this building was deemed at the time, it has been found incompetent to contain and exhibit, properly arranged, the numerous objects which have been added to the original collections. A new edifice has therefore been constructed in the garden, and is now nearly completed from designs by Mr Smirke; it forms a quadrangle 500 feet long and of just proportions, and which will, when completed, be the noblest pile in the metropolis.

From the limits to which this article is restricted, it is difficult to give even an abridgment of the valuable contents of this Museum, the synopsis of which alone fills near two hundred printed pages, and the descriptions of various departments, with the catalogues, occupy more than twenty quarto volumes. But the progress of the collection, even in an abridged form, is sufficiently interesting to deserve being sketched in this place. After the Cotton and the Sloane collections were obtained, the Harleian library and the noble acquisitions of Sir Simon d'Ewes were added, containing valuable Saxon manuscripts and other documents, with the possessions of Stowe the celebrated antiquarian. In 1767, the trustees were empowered to sell any duplicates of books, medals, or coins, and supplied with the amount to purchase others. In 1772, the Parliament voted L. 8410 for purchasing some antiquities brought from Italy, and, in 1804, L. 16,000 for building additional galleries and apartments for Egyptian and other articles; and a curious collection of antiquities from that country was bequeathed by Colonel Lethieulier. The widow of Maddox the historiographer, bequeathed the valuable collection of manuscripts which had been made by her husband. Major Edwards bequeathed many books and L. 7000 to purchase others, when the collections of Dr Birch were purchased; and, about the same time, Mr Da Costa presented many Hebrew manuscripts and several books, and Dr Cracherode a collection of the best Greek and Latin classics. Since that, additions have been made of the Greek coins of Mr R. Payne Knight, and presents of architectural and other casts from the Royal Academy. The valuable mineral collection of the Honourable C. Fulke Greville was purchased by the public, and also the rare classical library of Dr Burney. The Elgin marbles, collected during Lord Elgin's diplomatic residence in Constantinople, have been purchased for L. 35,000, and casts from them have been made and liberally presented to several public institutions in foreign countries. The Townley marbles have been a valuable addition, as well as the manuscripts of classical and other ancient authors, which belonged to that gentleman. Another addition has been made of a series of newspapers from 1603 to the present time, which form more than 7000 volumes; and also a collection of 300 or 400 volumes in quarto, forming materials for the history of the stage, and of actors and authors from the year 1600 to the present time. The most considerable accession made to the books was the library of his Majesty George III, presented to the institution by his son George IV. on his succeeding to the throne. It is highly valuable, as well for the number as for the rarity of the works, but especially of the maps. The whole is preserved in one of the magnificent rooms in the newly erected part of the building. See the article LIBRARIES.

The trustees, who have the management of this invaluable institution, are of three descriptions. The first are official trustees, consisting of the heads of the several departments of the government, of the law, of the church, and the presidents of the Royal Society, of the College of Physicians, of the Antiquarian Society, and of the Royal Academy. The second class, called family trustees, are two representatives of the Cotton family, two of the Harley family, and one each of the family of Townley, of that of Elgin, and that of Knight. The third class are called elected trustees, being chosen by the others, and include twelve names, the most distinguished in the kingdom for rank and talents.

The Museum is open to the inspection of the public from ten o'clock till four, except on Sundays, and on a few holidays, and during the months of August and September. No other regulation is made but that the visitors shall write their names and addresses in a book prepared for that purpose. A sufficient number of servants attends to preserve the valuables from injury, and to give any necessary information, and no money is allowed to be taken by any of them. Admission to the reading room may be obtained by application, in writing, specifying the name, abode, and profession of the applicant, which the librarian lays before the board at the next meeting, and if it be a person known a temporary ticket is immediately given; others must give a reference, or their application receives no attention. The tickets secure admission for six months, and must then be renewed. In the reading-rooms are convenient tables, furnished with writing materials and catalogues of the books. Any person who wishes to consult any work has only to write its title and his own name, and it is brought to him by the servant to whom the note is given (of whom there are abundance attending), with a dispatch that is not known in any other institution of the kind in Europe. Students who wish to make drawings in the galleries are admitted upon application in the same manner, but must produce a recommendation from a trustee, or from an officer of the institution, or from one of the professors of the Royal Academy. The number of visitors to the Museum, in 1834, was 237,000; the number of those who had tickets of admission to read was 70,200.

The decorations on the grand staircase and on the ceil-ng above it are worthy of observation, having been painted by artists of great skill and celebrity; and the new part the king's library is finished in the most chaste and appropriate manner. The rooms filled with mineral collections, the gallery of the Elgin marbles, and the other parts, are all calculated to excite delightful feelings.

At the beginning of the last century Marybone or Mary-ebone was a small village nearly a mile distant from any part of the metropolis. In the year 1715 a plan was formed for building Cavendish Square, and several other streets on he north side of the Tyburn Road. In the year 1717 or 1718 the ground was laid out, and a circle on the centre hen enclosed. The Duke of Chandos then took the whole northern side, intending to build a magnificent mansion, of which the two existing houses were to form the wings. Lord Harcourt and Lord Bingley took ground on the east nd west sides, and the remainder was let to builders; but he calamities which were caused by the South Sea bubble ended to retard the progress of the operations till 1726. The row of houses on the north side of the road to Tyburn was completed in 1729, and the name of Oxford Street given o it, and soon afterwards most of the streets leading to Cavendish Square and Oxford market were laid out. Mait-and says, that in 1739 there were 577 houses in the parish f Marylebone, and 35 families who kept their coaches; ut there still remained a considerable void between the ew buildings and the village, which consisted of pasture elds. Portman Square was begun about 1764, when the orthern side was built, but it was nearly twenty years be-ore the whole was finished. In 1770, the continuation of Harley Street commenced, and also Mansfield Street, the tter in a place where there was once a basin of water. Portland Place and the streets near it were built soon after-wards, and Stafford Place, in 1774, on a piece of ground be-nging to the city, on which the Lord Mayor's banqueting-ouse had formerly stood. Cumberland Place was begun bout the same time. During the war with America the ate of augmentation was very languid. But in 1786 a ew start was made, and Manchester Square, which had een commenced a few years before, was completed in 1788. Since that time the advance has been much greater nd recently more rapid. The first step was to build over hat was formerly the manor of Lilestone, but is now called isson Green, to the north-west of the other buildings. here several streets and some squares were filled with ouses, which, though upon a small scale, were for the ost ornamental and comfortable. From thence the houses ere carried on farther in the same direction to what was nown as St John's Wood, but is now called Portland Town, rom the title of the noble proprietor of the land. It is in his part that the magnificent rail-road from London to Bir-mingham has begun to be formed. Lofty mounds have been rected over valleys, and deep cuttings have been made hrough hills. The present appearance of the work, in 1836, excites surprise in the beholder, and the completion f it will become a very attractive object.

The most striking improvement which has been made in his quarter has been recently accomplished by covering ith elegant rows of buildings, villas, and other edifices, a ising piece of ground between the New Road and Hamp-tead. This land had been let on long leases by the crown, hich expired in 1814, when it was planned out for build-ing by that eminent artist, Mr Nash, and under his direc-ion accomplished in a few years. The whole has received he name of the Regent's Park. It is nearly a circle of 0 acres, laid out with shrubberies, adorned by a fine piece water, and intersected by roads, which are adapted for romenades, or for carriages. In the enclosures there are ome villas, and the greater part is surrounded with noble anges of buildings. To the south of the New Road is the remarkable pile of Park Crescent, a circular range of thirty elegant houses, in the centre of which Portland Place terminates. Across the New Road the first mass of erections is a neat quadrangular assemblage of twenty-four houses, called Park Square, on the east side of which is the adult orphan institution. To the eastward of this stands the Diorama, an object which has excited great curiosity and exquisite delight. The interior resembles that of a small theatre, the part allotted to spectators being boxes elevated three or four feet above the amphitheatre or pit. Above is a circular ceiling ornamented with transparent devices, and surrounded with medallions of eminent sculptors and painters. The whole is moveable, and is made to revolve with the spectators at intervals of a quarter of an hour, so that as one picture recedes, the other comes gradually into view. The effect produced by the disposition of the building, and by the various modifications of shade and light, renders the optical deception complete, and almost persuades the spectator that he is not contemplating a work of art. This striking production of art and of machinery was first opened in September 1823.

Near to this is the Colosseum, a name applied in consequence of the vastness of the buildings. It was erected in 1828 by Decimus Burton, and is one of the noblest edifices of the metropolis. It presents a Greek Doric portico of six columns, and is surmounted by a dome 120 feet in diameter, of which 75 feet are wholly of glass. Its form is that of a polygon with 16 faces, each of 25 feet, and the circumference of the whole building is 400 feet. The height of the walls on the outside is 64 feet, and on the inside 79 feet, whilst the sky-light of the dome is 112 feet from the ground. Beyond the entrance are vestibules, one of which leads to a saloon for the exhibition of works of art, and the other to the various galleries from which the panorama is to be viewed. There is also, in the centre of the building, a curious contrivance, by means of which visitors are raised at once to a level with the panorama, and saved the trouble of ascending the staircase. The panorama of London, which is here exhibited, far surpasses, in extent and accuracy, every thing of the kind that had before been attempted. Some idea of its size may be formed from its occupying 40,000 square feet, or nearly an acre of canvass. The various objects are depicted as seen from the top of St Paul's, where the original sketches were made, at the time when the ball and cross were being replaced. The gardens surrounding the building are laid out so as to appear much more extensive than they really are. They comprise conservatories. waterfalls, a Swiss cottage, and other interesting objects.

The next group beyond these public exhibitions is the smallest in the park, named Cambridge Terrace, consisting of ten houses, though the front appears as one building with a centre and two wings having porticos of the Roman or Pseudo-Doric order. Chester Terrace follows next, a grand and commanding range of buildings, consisting of forty houses; they are of the Corinthian order, and at each end of the terrace is an arch connecting them with the pavilion-shaped mansions. One of the finest ranges of buildings erected by Mr Nurse is considerably elevated above the road, and separated from it by a garden, round which is a sweep commanding a fine view of the park. It is named Cumberland Terrace, consisting of thirty-three houses, with a front in harmony with the whole. It has a centre and wings connected by two arches. The ground-story is rusticated, and, in the end, in the principal masses of the building, serves as a base for Doric columns, surmounted by a balustrade, on which are placed allegorical figures of the seasons, the arts and sciences, and other subjects. The central portion consists of a splendid colonnade of twelve columns, surmounted by a pediment containing sculpture, which represents Britannia crowned by fame, seated on a throne, at the base of which are figures representing valour and wisdom, and some similar emblematic subjects.

The next object, to the north, but still on the eastern side, is St Catherine's Hospital, founded by the queen of that name, the consort of Henry VIII. It was originally built near the Tower, but, upon the erection of the new docks, it was, in 1826, removed to the Regent's Park. The institution consists of a master, three brethren chaplains, three sisters, and ten poor women, who are maintained by funds provided by that queen, and increased since by other benefactions. The building is in the pointed style of architecture, and consists of two ranges, each forming three houses. In the centre is the collegiate church, elegantly fitted up within, and with a corresponding front, surmounted by two pinnacles. On the opposite side of the road is the house of the master, a handsome building surrounded by two acres of ornamental garden.

After passing Gloucester Gate, a neat structure, of the Doric order, consisting of four fluted columns, flanked by stone lodges, which leads to the great north road, the next object of attraction is the Zoological Garden. This establishment, consisting of the Gardens and the Menagerie, stands at the north-east corner of the Park. It was founded by a society of men of science in 1826, and this spot opened to the public two years after. The Gardens form a most agreeable promenade, and the collection preserved in appropriate dens, aviaries, and paddocks, is already large and constantly increasing. It is much frequented by visitors, 142,000 persons having been admitted in a year. It has been much enlarged in 1835 and 1836, and the arrival of four giraffes has drawn to it astonishing crowds.

The Regent's Canal crosses the park on the northern boundary, and over it is Macclesfield Bridge, a most elegant structure, consisting of three arches, supported by cast-iron pillars of the Doric order. On the next, or northwest side, are some elegant detached villas; that of the Marquis of Hertford is particularly an object of admiration. Hanover Terrace, on the west side, consists of nineteen houses, built by Mr Nash, forming an apparent continuous building. It consists of a centre and two wings of the Doric order, crowned with pediments surmounted by statues of the muses. In the central pediment is a group of figures in *relievo*, representing medicine, chemistry, architecture, sculpture, poetry, peace, justice, agriculture, plenty, music, history, and navigation.

Opposite this pile is a small gate, opening into the enclosed part of the park by a footpath, which winds into a serpentine form to a gate opposite to Sussex Place, and terminates at another gate fronting York Terrace. Sussex Place is rather a whimsical range of buildings, composed of twenty-four houses, consisting of a centre flanked by octagonal towers and wings with four similar towers, the whole being disposed in a semicircular form, with a garden in front. The towers are finished with cupola tops and minarets, which produce a singular effect. Near to Sussex Place is Clarence Terrace, a group of twelve houses, being the smallest in the park. It consists of two wings and a centre, of the Corinthian order, connected by colonnades of the Ionic order. Cornwall Terrace was one of the earliest ranges of building in the park, consisting of twenty-one houses. The basement is rusticated, and the upper part is adorned with fluted columns and pilasters, with well-proportioned capitals. This also is after the design of Decimus Burton. York Terrace is the largest, and one of the most splendid masses of building in the park, containing sixty-one dwelling houses, on a plan designed by Nash. The ground-story presents a range of semicircular-headed windows and rusticated piers, above which is a continued pedestal, divided between the columns into balustrades, in front of the windows of the principal story, to which they form balconies. This terrace appears more like a single palace than a row of separate dwellings, from all the doors being at the back of the buildings, and from the gardens in the front having no divisions. In the centre of the pile is York Gate, forming, with the two rows of mansions which flank it, a noble entrance to the park. Ulster Terrace, comprising seven houses at the western corner of Park Square, is a plain and simple range, adorned at the basement story with a colonnade of the Ionic order.

It has appeared desirable to give a more detailed description of the buildings in this part than can be allotted to similar objects in other parts of London, because it is unique in its plan, elegant in its execution, and, as a whole, presents a spectacle unrivalled either in Great Britain or in any of the cities of the continent.

The handsomest assemblage of houses in this district is Portland Place, terminating towards the north in an elegant circus, open to the Regent's Park. The houses are lofty, elegant, and regular, but differ somewhat in size, though none of them is small. They may be calculated for families whose expenses amount to from L.3000 to L.6000 per annum. Portland Place is about a furlong or eighth of a mile in length, and 126 feet in breadth, with a proportional breadth of foot pavement. It contains seventy-four large houses. The crescent, in which it terminates, has thirty elegant houses, and in it is a fine bronze statue of the late Duke of Kent, the work of Mr Gahagan, seven feet two inches in height, and weighing two tons.

Baker Street, which runs nearly parallel to Portland Place, is a fine street, about two-fifths of a mile in length, and containing ninety houses, besides fifty in the continuation of it, called Upper Baker Street. The houses vary much in size, but from the breadth of the street, the whole has a fine appearance. The intermediate streets between Baker Street and Portland Place, consist of neat but small houses, tolerably uniform in appearance, and are let at rents varying from L.80 to L.150 per annum. In Gloucester Place, and Upper Gloucester Place, to the west of Baker Street, are good assemblages of uniform houses, containing together 140 mansions, occupied by respectable families.

In this district are some of those fine squares which are the peculiar ornament of London, and are not to be seen in equal extent or elegance of building in any of the cities of the continent. Cavendish Square, the oldest of them, is adorned by a statue of William Duke of Cumberland. It contains several magnificent mansions, and a few of inferior extent. The total number of houses is thirty-seven. In the centre is a garden surrounded with iron palisades. Portman Square, with numerous streets around it, is built upon the estate of the Dorsetshire gentleman whose name it bears, and the value of it will be prodigious, when the present leases of the houses shall expire. The square contains forty first-rate houses, with a neat garden, of an oval shape, in the centre. Manchester Square, though of smaller extent than the others, and with houses of not quite so expensive a rate, is well built and neat. The north side is nearly occupied with the magnificent mansion of the Spanish Embassy, and near it is a handsome Roman Catholic chapel, very fully attended. It contains, besides the Spanish house, twenty-six others. Grosvenor Square is one of the oldest and most distinguished of the metropolis, as well for the size and the architecture of the houses, as for the number of the highest ranks of the nobility who reside in it, and the taste displayed in laying out the garden and shrubbery in its centre. It was built in 1726, by Sir R. Grosvenor. It contains six acres of land, and forty-four magnificent houses. In the centre is a gilt equestrian statue of King George I., executed by Van Nost.

Paddington.

The village of Paddington was about one mile from Tyburn, but by the great increase of houses of late years, it is now an undistinguishable portion of London. It, however, extends to the westward, and includes within its parochial boundaries the hamlet of Bays Water, and the part called Craven Hill. The parish was in ancient times a portion of the estate of the Abbot of Westminster, and the present church was then a chapel of ease to the church of St Margaret's, Westminster. The parish church in the centre of the green was consecrated in 1791. It is a handsome building upon a Grecian model, with a portico of the Doric order, and towards the south end a cupola on the top.

The general increase of inhabitants in this parish from 1800 to upwards of 15,000, has been in a great measure owing to the completion of the Grand Junction Canal, the company having constructed a capacious basin with wharfs and warehouses, in which a vast deal of business is transacted. The situation is very favourable to the extension of good houses, and accordingly many of those have been erected within the few last years in the different squares, streets, and places which have been constructed. Bryanstone, Dorset, and Montague squares are neat assemblages of houses, letting from L.160 to L.260 per annum. Cumberland Street, and others near it, present very elegant buildings, as do Connaught Terrace and Place, looking into Hyde Park. One portion is filled with villas, upon a small scale, in gardens known as Alpha Cottages, whilst beyond them, in what was called St John's Wood, and now destined to bear the name of Portland Town, new streets are laid out, which will probably, in a few years, be filled with handsome houses, and with numerous inhabitants.

The Clergy's Orphan School is now established in St John's, Wood-road. It is an old institution, established in 1749, but of late greatly increased, and incorporated in 1809, for the clothing, maintaining, and educating the orphan children of the clergy of the Established Church. A fine building has been erected, which is an ornament to the spot, and the institution is well and economically conducted.

One of the most striking objects in this new part of the metropolis is the Roman Catholic Church, newly erected upon a spot said to have been formerly occupied by the Knights of St John of Jerusalem. It has been built and endowed with funds for its maintenance by two pious sisters of the name of Galini. It is built in the style of the pointed architecture of the thirteenth century. The front is deemed one of the best modern adaptations of the materials furnished by our ancient ecclesiastical architecture that London presents; and, whilst the style is strictly adhered to, the composition is original, though the materials are taken from existing examples. The length of the church within the nave is 110 feet, that of the aisles 99 feet; the breadth of the body of the church is 44 feet, and the height 44 feet.

The basin of the Grand Junction Canal, the new market formed near it, and the large warehouses, have brought a great degree of trade to this quarter; whilst the Regent's Canal, which communicates with it, renders the conveyance of coal and other heavy substances cheaper than formerly.

One part of Paddington approaches near to the Royal Gardens and the Palace of Kensington. Kensington Palace, so called from its vicinity to the village of that name, stands within the parish of St Margaret's, Westminster. It was originally built by Sir Heneage Finch, afterwards Earl of Nottingham, and Lord Chancellor. His son, the second Earl, sold it to King William III. soon after his accession to the throne. This palace has been successively inhabited and improved by Queen Anne, and the two first Georges of the present dynasty. King William, Queen Anne, her consort George Prince of Denmark, and George II. here expired. During the first part of the reign of George III. none of the royal family made it their residence; but of later apartments have been assigned in it to the Duke of Sussex, who still occupies them, and since that time, another considerable part has been, and still is, occupied by the Duchess of Kent and her daughter the Princess Victoria, heiress-presumptive to the throne. The palace is a large irregular edifice, built at various times of red brick. The principal entrance is on the west side, and leads to some elegant and spacious apartments, one of which, called the cube-room, is 37 feet square. There are two fine galleries, one called the King's, 94 feet by 21; and the other called the Queen's, 84 feet by 21. The palace contains some pictures by the old masters, and many portraits. The great staircase, and the several ceilings, painted by the artist Kant, are much admired. The charm of this palace consists in the gardens in which it is placed, and which form a most refreshing resource to the inhabitants of London. They are more than three miles in circuit, and have, in addition to pure air, that variety of lawn, shade, and water, which make them a most delightful promenade; in summer a band of good music plays, and it is altogether one of the most agreeable, as well as most frequented, promenades in the vicinity of the metropolis.

Chelsea.

In the way from this to London, but a little to the south, is the large and populous village of Chelsea. Chelsea College was originally built in the reign of King James I., and was intended to be maintained as a polemical school of divinity. It was incorporated for that purpose in 1610, and consisted of a provost and twenty fellows, of whom eighteen were required to be in holy orders, and the other two, who might be either laymen or divines, were to be employed in writing annals of the times. Dr Sutcliffe was the first provost, and Camden and Haywood the first historians. Sutcliffe, who had counted upon voluntary supplies, and also on the effect of the king's letter, was to a great extent disappointed, and having proceeded far in the undertaking, was reduced to ruin. In consequence of a chancery suit the unfinished building fell to the crown, and in the civil war to ruins. After the Restoration, Charles II., in 1669, granted the site and the ruins to the Royal Society, at that time incorporated; but, having no funds to build with, it was again sold to the crown in 1682 for L.1300. It was then determined to erect an hospital for the reception and maintenance of maimed and superannuated soldiers. Sir Christopher Wren was the architect, and the work was completed in the year 1690, at the cost of L.150,000. Many of the nobility and clergy contributed largely, and donations have ever since been continually flowing in from various quarters. It is a fine building, with a front of 790 feet, and the gardens and ground are forty acres in extent. It is three sides of a quadrangle, in the centre of which is a bronze statue of the king who founded it. The east and west sides are occupied by the pensioners, who amount to upwards of 400 men, and are well clothed, lodged, and fed. The centre is on one side occupied by the chapel, and on the other by the halls; the former has a fine altar-piece, and the latter an historical painting by Sterrio, and also Ward's picture of the Battle of Waterloo. The governor has a spacious house with a state-room, containing portraits of Charles I. and II., of William III. and his consort, and of George II. and George III. Adjoining to it is an appropriate infirmary for the diseased.

Near to the hospital is the Royal Military Asylum, an institution for the maintenance of the orphan children of soldiers. It is an extensive and handsome building, forming three sides of a quadrangle. The principal part, which is on the west side, has a noble portico of four Doric pillars, supporting a pediment with the imperial arms. The centre consists of dining and school-rooms, and a dormitory. On the top is the telegraph, which communicates between the Admiralty and Portsmouth and Plymouth. This establishment at one time was a refuge for 700 boys and 300 girls, but has of late, from economical motives, been much reduced.

The new church at Chelsea, dedicated to St Luke, has already been noticed; and the old church of St Luke is now by law made a chapel of ease to the new building. In it, and the burial-ground surrounding it, there are many old and curious monuments to distinguished persons who have been interred there. This large parish, containing 35,000 inhabitants, has, by act of parliament, been divided into Upper and Lower Chelsea, as far as regards ecclesiastical matters, and a new church for the former has been erected in Sloane Street. It is a neat building, with two spires, and is capable of accommodating 1200 persons. It is dedicated to the Holy Trinity.

A small brook, now covered with an archway, divides Chelsea from the city of Westminster. A part of the parish of St George's, Hanover Square, is the first place which is entered on that side. A few years ago it was a large piece of swampy land belonging to Lord Grosvenor, since created Marquis of Westminster. It has been recently built upon, and already exhibits by far the best squares and streets of the metropolis, whilst engagements are entered into, and proceeding towards completion, which will in a few years render this a most striking mass of splendid houses.

Belgrave Square is completed, and is the most admired part of the undertaking. It is 684 feet long, and 617 wide; each of the fronts inward are uniform, and is adorned with columns of the Corinthian order. The centre houses are very magnificent; those on both sides of them are similar, but not so large, and all are finished in the most elegant manner. The latter have been sold for about L. 10,000 or L.12,000 each, when finished. Eaton Square, which is not yet completed on the south side, will form a parallelogram of 1637 feet by 371, with elegant gardens in the centre, and the beautiful portico of the new church of St Peter at the end. The streets leading from Belgrave Square, or near to it, are all new, and the houses are elegantly constructed. Wilton Crescent and Street have a tasteful appearance, and near them a new square is about to be built, to be called Lownd's Square, connected with Knightsbridge. On the south, between Eaton Square and the Thames, it is proposed to construct a new pile of buildings, to be called Chester Square. The whole of this district has been much favoured by a new access to that part of Westminster, where the two Houses of Parliament and the courts of law are situated, through the Birdcage Walk in St James's Park.

Buckingham Palace.

One of the most prominent objects in this district is the King's Palace in St James's Park, heretofore distinguished by the name of Buckingham House, from the noble proprietor John Sheffield, Duke of Buckingham, who erected a residence in what was then called the Mulberry Garden, in 1720. On the marriage of Queen Charlotte, the mother of his majesty William IV, this house was settled upon her; she continued her occupation of it many years, when it obtained the name of the Queen's Palace, and all her children were born there, with the exception of the oldest, afterwards George IV.

With a view to reparation, as was at first announced, money was voted by Parliament; but by some change of plan, instead of repairing the ancient building, a new one has been erected at the expense of nearly L. 700,000, exclusive of what may be required to finish and furnish it in a manner suitable for a royal residence. It is expected to be habitable by the end of the year 1836.[1]

This great work was designed by the late Mr Nash, but, before his death, it was superintended by Mr Blore, who made considerable alterations in the plan of his predecessor. The grand entrance of the palace looks on the canal in the park, and the view terminates with the building of the Horse Guards. It is through an arch of white marble, in imitation of that of Constantine in Rome, and is ornamented with sculpture, by Westmacott and Bailey. A semicular railing, ornamented with mosaic gold, extends to the two wings. The body of the palace is a parallelogram, from each end of which a wing is extended, thus forming three sides of a square. At the termination of the left wing are placed fine statues of History, Geography, and Astronomy, and on the right wing of Painting, Music, and Architecture. The pediment in the centre contains the royal arms, above which are statues of Neptune, Commerce, and Navigation. Around the whole of the building, and above the windows, is a frize, combining in a scroll the Rose, the Thistle, and the Shamrock.

The entrance hall, though low, is very splendid. It is paved with variegated marble, bordered with a scroll of sienna, and centered with puce-coloured rosettes. The walls are of scagliola, and the ceiling is supported by forty-four white marble pillars, decorated with Corinthian capitals of mosaic gold. Behind the hall is a vestibule of considerable length, against the sides of which are thirty-two columns, similar to those in the entrance-hall. In the centre of the vestibule is the door of the library, a handsome suite of three rooms looking into the garden; to the right are the apartments of the Queen, and the private staircase leading to them; and to the left are the King's study, and apartments for secretaries and attendants. Returning to the hall, the grand staircase is on the left, the steps of which are solid blocks of white marble, whilst the rail is richly formed of mosaic gold and mahogany. This staircase ascends on either side, and leads to the state rooms, which are very splendid. The three drawing-rooms are decorated with blue and red imitation marble columns, surmounted by gilt capitals; the floor of the ante-room is richly inlaid with holly and satin wood. The throne-room is richly gilt, the ceiling embossed with magnificence, and the frize contains bas-reliefs by Bayley, after designs by Stothard, representing the wars of York and Lancaster. The imperial throne is placed in an alcove at the end of the apartment. From this splendid room a door leads into the picture gallery, a noble saloon running the whole length of the palace, being 164 feet by 24. It is lighted by three parallel ranges of sky-lights, decorated with tracery and oriental pendants, presenting a very pleasing appearance. Over the mantle-pieces are carved heads of the celebrated artists of antiquity, and the floor is formed of pannelled oak. The dining-room is richly adorned, but by some is deemed of insufficient capacity for royal banquets.

The front of this palace, which is the most pleasing, is that from the garden. It is chaste and simple. A sheet of water and a shrubbery have been formed before it, and the entrance this way is through the magnificent triumphal arch, designed by Nash. This arch is of the Corinthian order. Towards Hyde Park are four columns, two at each side of the arch supporting a portico. The arch itself is adorned with six Corinthian pilasters. The front towards the garden is exactly similar. The vaulted part in the centre is divided into compartments, richly sculptured. A small doorway on each side leads to the porter's apartment, within which are stairs leading to the top. Along the entablature are placed G. R. and the imperial crown. The gates, of bronzed iron-work, are beautiful, and adorned with the royal arms.

Hyde Park.

Hyde Park is entered by a fine triumphal gate, opposite to that which leads to the garden front of the royal palace. This gate, designed by Decimus Burton, and executed in 1826, consists of a screen of fluted Ionic pillars, with three archways for carriages, two for foot-passengers, and a lodge. The whole frontage is 107 feet. The central gateway is adorned with four columns, supporting the entablature, above which is a frize running round the four sides of the structure. This frize represents a naval and military triumphal procession. The side gateways present two insulated Ionic columns, flanked by antæ. The gates are beautiful specimens of bronzed iron-work, and the whole fabric has a most magnificent effect. The park consists of 95 acres in extent, and is a most valuable appendage to the metropolis, by the advantageous means of recreation which it affords both to pedestrians and equestrians. At the entrance from Piccadilly is the colossal statue of Achilles, in bronze, executed by Westmacott, cast from cannon taken by the Duke of Wellington, to whom it is dedicated, at Salamanca, Vittoria, Toulouse, and Waterloo. It stands on a base of granite, is eighteen feet in height, and is said to weigh thirty tons. One part of this park is used for reviewing troops, and another part is covered with the Serpentine River, which, when frozen, affords very great gratification to the practitioners and admirers of skating.

The finest entrance to London is by Hyde Park corner into Piccadilly. The street is nearly a mile in length (680 yards), but, from inequalities, can nowhere be seen at one view. It terminates at the other end, in the elegant circus, where the two parts of Regent Street meet, which street is exactly a mile long. At its lower end, in Waterloo Place, is the Duke of York's Column. A colossal bronze statue of that prince, executed by Westmacott, has been placed on a podium rising out of the summit of this column. It is a fine bold composition, with full drapery falling down the back of the figure, and giving it breadth and importance. The figure looks towards the parade ground of the Horse Guards, and the back consequently is presented to the view from Regent Street, and the United Service, Athenæum, and other club-houses. The column is of pale red granite, 150 feet in height, and may be ascended by a spiral staircase within. At its foot is a fine flight of steps leading into St James's Park.

Recent alterations have much improved the adjoining spot, on which Carlton Palace stood. Besides a stately range of elegant buildings upon the site of the palace, a handsome square has been formed. The front towards St James's Park consists of sixteen houses, which are disposed in two ranges, raised on a substructure, which contains the kitchens and domestic offices, forming a terrace about fifty feet wide, adorned with Pæstum Doric pillars, surmounted by a balustrade. The superstructure consists of three stories, ornamented with Corinthian columns. On descending the steps into St James's Park, the view of that pleasing ground is fine, shewing the course of the water, the islands in it, with the shrubberies and the gravel walks, as well as the road from the royal palace to the Horse Guards, by which the King passes in state to the parliament-house.

The parade place for the Guards is a fine opening, and at each side are placed trophies of war, particularly two prodigious pieces of artillery, whilst the esplanade terminates with that strong and handsome stone building, in which the troops in immediate attendance on the King are quartered, two of whom, on horseback, act as sentinels, in two lodges in front of Whitehall. In this building is the office of the commander-in-chief of the army.

On emerging from the gate of the Horse Guards, the celebrated banqueting-house, built by Inigo Jones, presents itself. It is an elegant and magnificent structure of hewn stone, adorned with an upper and lower range of pillars, of the Ionic and composite order. The capitals, and the space between the columns of the windows, are enriched with fruit and foliage. It is surrounded with a balustrade, and the whole exterior has been put in a complete state of repair. The interior consists chiefly of one apartment, of an oblong form, about forty feet in height. The ceiling was painted by Rubens, and represents the apotheosis of James I. It is now an elegant chapel, in which divine public worship is performed every Sunday. It is adorned with the eagles and other trophies taken from the French in Spain, which were deposited here with great military ceremony in May 1811. Charles I. was led from this building, through a window in the front of it, to the scaffold, where he was executed on the 30th January 1649. In the gardens between this building and the river, there are some dwellings of persons of the highest rank; and in one part a public building has been given up by the government, to form the museum of the United Services. A valuable collection has been formed, by the zeal of the officers of the army and navy, and is receiving daily augmentations. It already contains many valuable and curious objects, not only such as are connected with those professions, but also in natural history, and in articles illustrative of the customs and manners of the distant countries explored by our adventurous countrymen.

London.

Public Offices.

Between the Horse Guards and Charing Cross is the Office of the Paymaster of the Forces, which, though conveniently arranged for its intended purpose, has no peculiar claim to attention from its architecture; but, adjoining to it, is that fine pile, the Admiralty Office, built on the site of Wallingford House, and celebrated for the councils held there by Oliver Cromwell and his officers. The front has two deep wings, and a lofty portico, supported by four large stone pillars of the Ionic order. There is a screen in front of the court, richly ornamented with naval emblems. The entrance of the main building is a spacious hall, from which are passages leading to staircases, by which the numerous offices are reached. There is a fine board-room, and within the building are numerous residences for the junior lords. On the top of it is the telegraph, which maintains the correspondence with the great ports where there are naval arsenals.

In Whitehall, next below the Horse Guards, is the entrance, by a gateway common to both, and whose Gothic architecture is much admired, to the Office of the Secretary of State for the Home Department, and the Treasury Office. The first has some of its apartments looking on the street, but that part is more remarkable for its antique than its beautiful architecture. The interior is arranged very appropriately, but it is rather too small for the increased business to be transacted. The Treasury is a fine large stone building, with its front towards the Parade. It is a portion of the old palace erected by Cardinal Wolsey, and altered at subsequent periods, but chiefly in the reign of Charles II. It displays in its front the Tuscan, Doric, and Ionic order of architecture, and the whole is surrounded by a pediment. The board-room is a fine apartment; but all the other parts are too much crowded, for the number of clerks that are necessary. From this office there is a communication with the official residence of the First Lord of the Treasury.

The building next to these in Whitehall, is the elegant recently-erected Office of the Privy Council and of the Board of Trade, finished in 1826, from the design of Sir John Sloane. Upon the left hand, or western side, are the offices for the clerks of the privy council, and their subordinates, whence proclamations are issued, and patents are prepared. Upon the first floor is the beautiful court where the privy council sit as a court of law, to decide on appeals from the colonial courts, or on other business referred to them by the king. The interior is simply, yet beautifully finished, and around it are rooms for the president, and others for the advocates and agents. The right side of the building is occupied by the committee of privy council for affairs of trade. The several rooms for the president, vice-president, secretaries, and clerks, are on both sides of a gallery, which extends the whole length of the building. In the construction of this part, the architect has preserved the old board-room, erected in the reign of William III., in order to retain the beautifully carved ceiling then placed there. A communication, by a gallery, is maintained between these offices and that of the Home Secretary and the Treasury.

In Downing Street, of which the council-office forms one corner, is, on the right hand side, the house for the residence of the First Lord of the Treasury, a noble mansion, with its best apartments looking into St James's Park; and, adjoining to it, another upon a smaller scale, occupied by the Chancellor of the Exchequer, when that office and that of First Lord of the Treasury are not filled by the same individual, but otherwise by one of the secretaries of the treasury.

At the bottom of the same narrow street, but with its best front towards the Park, is the office of the Secretary of State for the Colonies and for War. The building has nothing in its exterior to engage attention, but it contains some fine apartments, and others very conveniently arranged for the despatch of business, and has been of late years extended by the addition of the house which was formerly the office of the Judge Advocate.

In the same street, touching the Colonial Office, and forming a right angle with it, is the office of the Secretary of State for foreign affairs. It has been formed out of several houses in addition to the old building, and presents to view neither regularity nor architectural beauty; in its appearance it is unworthy the dignified business there transacted, where the representatives of all the states of the civilized world have constant occasion to repair, and where the cabinet councils are most commonly held. It is, however, if not imposing, very appropriately fitted up in the interior, with noble apartments for the chief and under secretaries, where they receive the foreign diplomatists; and of late years the part occupied as a dwelling has been repaired, beautified, and elegantly furnished, and as such was first used as a residence by Mr Canning for a very short time before his death.

In Duke Street, Westminster, near to Downing Street, and looking on the Park, a new and noble building has just been finished as a State Paper Office. It has a handsome front, secured against any accident by fire, and well arranged for the purpose of preserving and rendering easily accessible the valuable documents which were removed to it from the old building in George Street. These papers can only be examined by a special order from the Secretary of State for the Home Department, which is generally granted on application, when asked, for any purely historical purpose, and every inquirer for such objects finds all the assistance he can desire upon the part of the officers of the establishment.

Houses of Parliament.

Westminster Hall has already been noticed; but the two Houses of Parliament were so much injured by the fire which accidentally broke out there in November 1834, as to render it necessary to make use of such apartments as could be most speedily converted to the purpose, for the accommodation of the two legislative bodies. A variety of suggestions have been offered for repairing or building anew the parts which were injured; but no decisive plan has been adopted, and for the present the House of Lords assembles in an apartment not very appropriate, and the House of Commons holds their sittings in what was the House of Lords, with such temporary repairs as the short time allowed for the purpose would admit. See the article WESTMINSTER.

Near to the parliament houses, in Cannon Row, is a neat and elegant building, but little seen at present, which is occupied by the Board of Controul for Indian affairs. It was built during the war for the Transport Board, which was abolished at the peace, and since that time it has been applied to its present use. It is a handsome building, with a fine portico of the Ionic order, its back front towards the Thames, and with apartments appropriately laid out.

Improvements.

Some of the greatest improvements made in the metropolis of late years have been projected or completed in the vicinity of Charing Cross, and along the Strand. All the old buildings at Charing Cross opposite to Northumberland House, including the western side of St Martin's Lane, have been removed. The new Golden Cross Inn has been completed, and the houses forming the east side of what is called Trafalgar Square are occupied. On the northern side of that square the new national gallery of painting, sculpture, and architecture has considerably advanced. It is being erected on the spot formerly occupied by the king's mews, but removed farther back, in order to give a better view from Pall Mall of the fine portico of St Martin's church. The part of the gallery towards the east has its front nearly finished, but before its completion it would be unfair to criticise the architecture. The gallery is intended to be about 500 feet in length, and will consist of a central portico of eight Corinthian columns in front and two in depth, ascended by steps at each end at an elevation of eight feet from the ground. Between the centre and the wings will be two entrances, composed of four Corinthian columns, one leading to Castle Street, and the other to the barracks. It is designed to have windows in the lower story for lighting those apartments, and in the upper story there are to be niches for statues. The portico will be surmounted by an ornamental dome, and the whole range of building by a balustrade. The part upon the right side of the portico will be devoted to the Royal Academy, and that to the left will comprise the galleries for the works of art; these being connected by the grand staircase and vestibule dividing the building into two parts.

The beautiful equestrian statue of Charles I. remains on the ancient spot, and it has been suggested that between it and the gallery some object should be placed which might do credit to the taste of the age.

The widening of the Strand, by removing Exeter Change, and many other obstructions, has made the West Strand a noble street; whilst the beautiful streets, called Adelaide Street and King William Street, have together contributed with the elegant Lowther Arcade, the Ophthalmic Hospital, the Charingcross Hospital, and many private houses, to change the character of that part of the town; especially by removing some hundreds of wretched houses, (in courts and alleys), which were the haunts of the most depraved portion of the population.

The new Hungerford Market already noticed, has now a good approach from the Strand nearly completed, which forms an additional improvement to the appearance of the western part of that street.

Somerset House.

Somerset House, or rather, Somerset Palace, is a pile of building standing on the site of a number of edifices, which were most tyrannically destroyed by the Duke of Somerset, who was protector in the reign of Edward VI., and ultimately the victim of his ambition and treason. The palace was begun in the year 1549, and the architect was one John of Padua, who was appointed in the reign of Henry VIII., under the title of Devisor of his Majesty's buildings. The architecture was that mixture of Grecian and Gothic, which had been introduced into England in the preceding reign. It was a spacious and magnificent edifice, and as by death it devolved on the crown, it was made use of as a residence for some members of the royal family. Queen Elizabeth resided here with her kinsman Lord Hunsdon. A chapel was begun by Inigo Jones, who had built the back, front, and the water gate. It was intended for the use of the Catholic Infanta of Spain, who was expected to become the wife of Charles I., when Prince of Wales; and though that match did not take place, it was used by the professors of the Catholic religion, and amongst others by the Queen Henrietta Maria. It was also the residence of the queen of Charles II., who was thereby removed from the observation of her royal consort's gallantries. It was at that time that it became he theatre of an irritating plot, probably founded on fiction, but which produced national agitation. Whether Sir Edmonbury Godfrey was murdered or destroyed himself, was, and must ever remain, a matter of doubt.

The present building is after a design of the late Sir William Chambers, and was begun in 1775. It occupies space about 800 feet wide and 300 deep, and forms a uadrangle, with a spacious court in the centre. The front owards the street consists of a rustic basement of nine rches, supporting Corinthian columns, surmounted in the entre by an attic, and, at the extremities, by a ballustrade. The key-stones of the arches are adorned with colossal masks in alto relievo, emblematical of the Ocean, and the ight principal rivers of England. On the three central windows of the first floor are medallions of George III., his Queen, and the Prince of Wales. The attic is divided into hree parts, by four statues, representing Justice, Truth, Valour, and Moderation, with the appropriate emblems of he scales, the mirror, the sword, and the bridle in one hand, nd the fasces in the other. The whole is surmounted by he British arms, supported by Fame, and the genius of ngland. The front towards the river is a spacious terrace. This river front has now two wings, built uniformly; that n the east side is a part of King's College, at the expense f which it has been recently completed, after having been ft for nearly sixty years a vacant and disgraceful spot.

The front part of the pile is occupied by the Royal Aca-emy, who have in it their annual exhibitions of painting, ulpture, and architecture. The other part, the Royal ociety, the Antiquarian Society, and the Geological So-ety at present occupy. The three other sides of the uadrangle are destined to the use of the Navy Board, the reasurer of which has an official residence looking on the ver; and some other houses in the same wing are occu-ed by Officers under the Admiralty. The Board of Taxes, ith its Secretary, have the use of a large portion; and the emainder is under the Board of Stamps, where the ma-inery is worked in their operations.

In this part of the town are a few objects which deserve otice, and which may here, as appropriately as in any other art, receive it. Covent Garden has already been noticed s a market for fruit, vegetables, and flowers. It occupies ree acres of land, covered with more elegant buildings han are usually to be seen in market-places; and it is, on the orthern, and a part of the eastern side, bounded by a range f handsome buildings, planned by Inigo Jones, on arches, ith a good walk or piazza under them. The greater part f these houses are used as taverns or coffee-houses. The hurch of St Paul, at the west end, has a fine portico, under which the elections of members of parliament for the ty of Westminster are held. This place was, in former mes, the garden of the convent of St Paul's, and was, on he suppression of those institutions, given to the family of Russell, whose successor, the Duke of Bedford, is the present possessor, and has rebuilt the centre, from plans by Mr owler, in 1829 and 1830.

Lincoln's-Inn-Fields is one of the largest squares in the metropolis; but the appearance is not favourable. The astern side has no other building but the wall of Lincoln's-Inn Garden. The north side consists of small, and mostly homely houses; but on the south and west sides are several noble mansions of considerable age, some used as offices by public boards, and others let out in chambers, like those of the Inns of Court. These houses have been inhabited by some of the most distinguished statesmen and lawyers of the country. Within the few last years Sir John Soane has presented to the public his house on the north side of the square, with the valuable collection of curiosities, which, in the course of a long life, he has been able to draw from various sources.

Leicester Square, like Lincoln's-Inn, is more remarkable for its extent than for its beauty. The greater part of the houses are upon a small scale, and not distinguished by any architectural taste. On the north side were once some distinguished edifices, particularly one the residence of Frederick Prince of Wales, father of George III., which was afterwards used for the exhibition of Sir Ashton Lever's museum. This square was the residence of Sir Joshua Reynolds, and of Hogarth, and Woollet, celebrated artists; and of John Hunter, the celebrated anatomist and surgeon. In the centre is a fine bronze equestrian statue of King George I.

In proceeding westward from Leicester Square, that singular pile of buildings, called from its form the Quadrant, is entered. It is a break in Regent Street, extending from Piccadilly to Glasshouse Street. This circular mass is ornamented by colonnades, with a good walk under a gallery surrounding the whole, which is supported by cast-iron pillars. The outward effect is fine, but the houses are not admired as residences, and have not been very advantageously occupied.

Between the Quadrant and Bond Street is Hanover Square, which was built in honour of the present royal family, soon after their accession to the throne. It occupies about two acres, has some noble houses but not in the best style, and is chiefly remarkable for a handsome suite of apartments, fitted up in the most splendid manner, and let out for the performance of concerts, or other public purposes. On the eastern side is a bronze colossal statue of William Pitt, executed by Chantrey. It is twelve feet in height, and stands on a pedestal of granite, fifteen feet high. The resemblance is very striking.

To the westward of Bond Street, Berkeley Square presents itself. There are only houses on three sides of it, as the wall of the noble mansion of the Marquis of Lansdowne, occupies the whole of the south side. The garden in the centre of the Square contains about three acres. There are in the whole, including Lansdowne House, fifty-four dwellings, several of them of the first class, but on the east side some of them are of a much lower description.

By crossing Piccadilly, St James's Square is arrived at. It has much celebrity, as well from the magnificence of several houses, and the eminent men who have lived in them, as from its being one of the oldest of the larger squares, and that which led to the practice of forming such places upon an extensive scale. On the south side, the back of some of the houses of Pall Mall, mixed with some small dwelling-houses, intrude on the view; but the other three sides are occupied by mansions of the very first class. The whole number of these is only twenty-four. The centre is a neat garden, laid out with shrubs, and, in the middle of it, there is a sheet of water, from which there rises a pedestal surmounted by a statue of King William III. The largest of the houses, are London House, belonging to the Bishop of London; and those of the Duke of Norfolk, Marquis of Bristol, Earl de Grey, Duke of Cleveland, Earl of Hardwicke, Bishop of Winchester, Earl of Dartmouth, Earl of Litchfield, Lord Rosslyn, Sir Watkin Williams Wynn, and Mr Hudson Gurney.

Palace of St James's.

The Royal Palace of St James, in Pall-Mall, has so long been treated as an object of consideration, by all the diplomatists of Europe, as to deserve a particular description. This palace was originally an hospital dedicated to St James, founded by some pious citizens before the Norman conquest. It was designed to receive fourteen lepers, to whom were afterwards added eight brethren, who were to perform divine service. It was rebuilt in the time of Henry III. The custody of it was conferred on Eton College, by a grant of the twenty-eighth year of Henry VI.; but it is reported, that the living of Chattesham in Suffolk was given in exchange for it, the college, on this consideration, having resigned it to Henry VIII. At that time the revenue was estimated at L. 100 per annum. The present building was erected by that monarch soon after the transaction, which took place in the year 1531, and was described by the historian Stowe, as "a goodly manor." The same king also enclosed the park, which became subservient to the amusement of this and the other palace of Whitehall. Charles II. who was particularly fond of it, planted the avenues, and formed the canal, and the aviary adjacent to the Bird-cage Walk, which took its name from the cages which were hung on the trees. The king, according to Cibber, was often seen here, amidst crowds of spectators, feeding his ducks, and playing with his dogs, and passing his idle time in conversation with the meanest of his subjects, which made him be adored by the common people. There exists no proof that this palace was regularly inhabited by any of our monarchs till after the fire in 1695, by which the palace of Whitehall was destroyed. James I. presented it to his promising son, Prince Henry, who resided in it until his death in 1612. Charles I. was brought to it from Windsor, on the 19th of January, by the power of the army, which had determined on his death, and his apartment was hastily furnished by his own servant, Mr Kinnersley of the wardrobe. Of the eleven days which he was permitted to live, some were spent in Westminster Hall, and the nights were passed in the house of Sir Robert Cotton, near the place of his trial. On the 27th he was carried back to St James's, where he passed his three last days in the exercise of exemplary piety. On the 30th he was brought to the place of execution; and walked, unmoved by every insult, with a firm and quick pace, supported by the most lively sentiments of religion. His son, the bigoted James, sent to the Prince of Orange, when he had approached in force near to the capital, an invitation to take up his lodging in this palace. The prince accepted it; but, at the same time, hinted to the frightened king, that he must leave Whitehall. It was customary to mount guard at both the palaces. The old hero, Lord Craven, was upon duty at the time when the Dutch guards were moving through the Park, to relieve those at Whitehall, by order of their master. From a point of honour, he determined not to quit his post, and was preparing to maintain it; but, receiving the commands of his sovereign, he reluctantly withdrew his party, and marched away with sullen dignity.[1]

During the reign of King William, this palace was fitted up for the residence of the Princess Anne, afterwards queen, and her husband Prince George of Denmark; and from that time to the present it has been regularly the court of the successive monarchs. Pennant, who described it about fifty years ago, and from whom a part of the preceding account is extracted, says, "Uncreditable as the outside of St James's Palace may look, it is said to be the most commodious for regal parade of any palace in Europe. The furniture of this palace is unbecoming the place." In this last respect very great improvements have been effected since that author took his interesting walks through London. It is still an irregular brick building of no external beauty, the front of a small part of which, in the form of a gateway, alone appears from the street, but the state apartments look towards the park. These are but one story in height, and appear tolerably regular, though somewhat mean. The south-east wing, in which were the apartments of the maids of honour, was destroyed by an accidental fire in 1809, and has not since been rebuilt. Between 1821 and 1824 the whole of the state apartments have been completely repaired and newly furnished, and thus put in the state now to be described.

These apartments are entered by a passage and staircase of great simplicity. The walls are distempered, of a dead stone colour, and are lighted by Grecian bronze lights, with moon shades placed on plain granite pedestals, which have an air of quakerly neatness, quite in unison with this part of the edifice. The exterior walls are sprinkled with black, in imitation of granite. On ascending is seen a sort of gallery or guard-room, converted into an armoury, the walls of which are decorated with daggers, swords, and musquets, in various devices. When a drawing-room is held, this apartment is occupied by the yeomen of the guard in full costume, with their battle-axes in their hands. The next room is a small chamber covered with tapestry, in fine preservation, from the ceiling of which an elegant chandelier depends. When a drawing-room is held, a person attends here to receive the cards containing the names of the parties to be presented, with the circumstances under which the presentation takes place. A duplicate of the card is subsequently handed to the lord in waiting, in order to prevent the introduction of improper persons. The next is the first of a succession of apartments, the last of which is the Presence Chamber. It is fitted up in a style of magnificent splendour. The walls are covered with crimson damask, and the window curtains are of the same material. The cornices and basements are formed of broad carved and gilt moulding, and extend to every part of the room. On entering, the eye of the spectator is first attracted by a looking-glass of unusual magnitude, which reaches completely from the ceiling to the floor. At the east end of the room is a painting of George II. in his parliamentary robes, and on the other walls hang two large pictures of Tournay and of Lisle. The furniture consists of sofas, ottomans, and stools, covered with crimson velvet trimmed with gold lace. From the ceiling hangs a superb or-molu lustre, containing two rows of lights of three branches each; and at each end of the apartment are two splendid candelabras elegantly gilt, calculated to receive twelve lights each.

The next room is fitted up in the same style of decoration, and contains an excellent full-length portrait of George III. in the robes of his order. On each side of these are two paintings of the celebrated sea-fights of Lord Howe on the first June, and of Lord Nelson at Trafalgar. The brilliant effect of the whole is considerably heightened by the addition of three magnificent pier-glasses, reaching from the floor to the ceiling. From the middle of the ceiling also hangs a delicately chased Grecian lustre.

The third and last room is the Presence Chamber, in which the king holds his drawing-rooms. This, in point of gorgeous decoration, far exceeds that of the preceding apartments, although the style is somewhat similar. The throne is splendid, and, in point of size and magnificence of effect, far exceeds that in the House of Lords. It is composed of rich Genoa velvet, thickly covered with gold lace, and is surmounted by a canopy of the same material, on the inside of which is a star embroidered in gold. There are three steps for his Majesty to ascend, which lead to a state chair of exquisite workmanship; close to which is a footstool to correspond. Over the fire-place is a full-length portrait of George IV. in his coronation robes, by Sir Thomas Lawrence. Upon each side of this picture are paintings of the battles of Vittoria and Waterloo. The piers of the room ndon

---

[1] James, the son of James II, who so long made pretensions to the British throne, was born in the room now called the old bed-chamber, at present the antichamber to the levee room. The bed stood close to the door of a back stair which descends to an inner court. It certainly was very convenient to carry on any secret design, and might favour the silly warming-pan story, had not the bed been surrounded by twenty of the privy-council, four other men of rank, and twenty ladies, besides other attendants. James, with imprudent pride, neglected to disprove the tale, and it was adopted by a party, and perhaps believed by some credulous zealots.

are entirely fitted up with plate-glass, before which are some beautiful marble slabs. The window curtains are of crimson satin, trimmed with gold-coloured fringe and lace. The cornices, mouldings, &c. are richly gilt, and the other embellishments and furniture, of corresponding elegance, present a coup d'œil in every way suited to the dignity and splendour of the British court.

Behind the Presence Chamber is his Majesty's closet, in which he gives audience and receives the members of his own family, foreign ambassadors, cabinet ministers, and officers of state. It contains a state chair and footstool; an elegant writing-table with a buhl inkstand, and other useful furniture. The king's dressing or private room is beyond this. The dining-room belongs to another suite of apartments, and is admirably fitted up and furnished. Many of the sleeping-rooms are in the house built by William IV. when Duke of Clarence, which has been united by a gallery with the palace. Some members of the royal family have suites of apartments within the palace, as well as the great officers of the household and the guards on duty. There is a chapel for the household and also a German chapel, where divine service is performed after the Lutheran form in the German language.

beth

In passing by Westminster Bridge to the right bank of the Thames, we reach the newly erected borough of Lambeth, where the palace belonging to the Archiepiscopal see of Canterbury is well entitled to notice.

Lambeth, in the earliest period of which there are any accounts, was a royal manor, and had a palace, in which King Hardycanute died, after a feast, in 804, and where Harold is said to have seized the crown, and placed it upon his own head. It was then a part of the estate of Goda, who became successively the wife of Walter Earl of Mantis, and of Eustace Earl of Boulogne; she presented it to the church of Rochester, but reserved to herself the ecclesiastical patronage. It became, in 1197, the property of the see of Canterbury, by exchange with Rochester; but the bishop of the latter preserved a small piece of land, on which a house was built for the residence of the bishops, when they were attending on parliament, called Rochester Place. One of the bishops, John de Shepy, in 1357, built Stangate Stairs, to accommodate himself and his retinue, when he had occasion to cross the river to Westminster.

The palace had been built by Bishop Boniface near two centuries before, but, between 1414 and 1443, was much improved by the munificent Bishop Chichley. He founded the Lollards' Tower, which was a prison for those suspected of heresy, in which are still to be seen rings, to which it is said the followers of Wickliffe were fastened when tortured. Hilsley and Fisher occupied this palace when it fell into the hands of Henry VIII., who exchanged it with the Bishop of Carlisle for some houses in the Strand, and it was then known by the name of Carlisle House.

During the civil wars in the reign of Charles I., Lambeth, like other ecclesiastical property, suffered severely. The fine works of art, and the sacred memorials of the dead, were in most cases sacrificed to puritanical barbarism; so that when, after the restoration, Juxon was appointed to the see, he found it a heap of ruins. During his short primacy, he did much to restore it to its former condition, and built a noble apartment, which was afterwards converted into a library.

The founder of the library was Archbishop Bancroft, who left to it all his books, as did his successor Abbot; and it has been increased by the several eminent prelates who have since filled the see, so that at present the collection contains more than twenty-five thousand volumes, besides many valuable manuscripts. (See the Article LIBRARIES.) When the long parliament had abolished episcopacy, and the palace was delivered to one of their party, the regicide cott, this valuable library was preserved from destruction, or at least from dispersion, by the discreet and dexterous management of the celebrated Selden. It appears by the bequest of Bancroft, that, in the event of his successors failing to give bond to deliver the books entire from one to the other, they should be given up to Chelsea Hospital. Two years after the execution of Archbishop Laud, the books still remained at Lambeth, when Selden, alarmed for their safety, suggested to the University of Cambridge their right to them. On the claim being made, it was acquiesced in, and the whole were removed to Cambridge. Juxon made application to have the books restored to the original repository, and, though not immediately surrendered, they were so soon afterwards, when Archbishop Sheldon filled the see. That prelate, as well as Tennison, Secker, and Cornwallis, made several additions of considerable value to the library; and almost every one who has held the dignity has been a contributor to the store. This noble collection of books, now exceeding 25,000 volumes, is placed in Juxon's hall, a fine apartment, forming part of the ancient palace. There is a chapel and a vestry adjoining, in which are many portraits of several prelates, and in the banqueting-hall are portraits of all the archbishops from Laud to the present dignitary. By the magnificence and taste of the present archbishop, the domestic part of the palace has been greatly enlarged; a new Gothic wing of great beauty, designed by Mr Blore, having been erected at an expense of more than L.52,000. The whole of the interior is fitted up in a style of simple beauty, oak pannelling pervading the edifice, and contrasting finely with the fretted ceilings and ornaments. The study of the archbishop is a noble apartment, forty feet by twenty; the drawing-room is also of fine proportions, commanding, from the ample bay-window, a pleasing prospect of the gardens, and a peep at the abbey and the bridge through the foliage.

London.

Not far from Lambeth is the Surrey Zoological Garden, in which there is a collection of various animals, with a den and pole for bears, a cottage for the wapiti and camel, a ruin for eagles, folds for deer, and a variety of sheds, &c. for various beasts and birds. There is a fine piece of water, and an elegant circular glass-house surrounding the cages of the animals. The whole is laid out with much taste, and excites great delight in the visitors.

Corporation of London.

Though the government of the far greater portion of the metropolis is under the immediate direction of the Secretary of State for the Home Department, and is administered by means of the magistrates and the police; yet that part which is usually denominated the city, and which is in the strictest sense London, is under the superintendence of an ancient corporation, which possesses great power and extensive property, and is therefore entitled to a somewhat minute description.

The rise of the corporation has already been traced, in the historical view at the commencement of this article. In its frame it bears a strong resemblance to the British constitution. It is composed of three grades; of a Lord Mayor, the executive officer, of a permanent body, the court of aldermen, and an annually-appointed body, the court of common-council In the latter body the aldermen have seats and votes, and therein it differs from the relation that exists between the Lords and Commons. All of these are chosen by the citizens by a majority of votes, when the choice is not determined by the show of hands. The Lord Mayor is chosen annually, but is capable of being re-elected. The right of voting for this dignity is restricted to those freemen who have been admitted into the livery of their respective companies. The restrictions on the choice are, that the person proposed to fill it must be an alderman, must have previously served the office of sheriff, and must be one of two chosen by the livery, and returned to the court of aldermen, who finally determine which of the two shall be invested with the dignity. The aldermen are appointed during life. They are chosen for a particular division of the city, called the ward, and in the election all resident freemen are entitled to a vote, whether they have been admitted into the livery of their companies or not. After the election, however, the court of aldermen has the power of rejecting the individual as a member of their body, in which case the election is declared void, and another must be made choice of. If, at the second election, the same person have a majority of votes, those votes are considered as null, and the next on the poll is invested with the dignity. From this choice an appeal may be made to the Court of King's Bench, when the reason for the rejection must be made out to the satisfaction of that tribunal, as happened in the only instance which occurred in modern times. The city is divided into twenty-six wards, each of which has its alderman, and a deputy appointed by him. One of these wards, called the Bridge Without, which was composed of the houses standing on London Bridge, has long ceased to contain any habitations, and the senior alderman is always removed from the ward which chose him, and is installed as alderman of the Bridge ward, and his former place filled by a new choice.

The whole of the common council is chosen on St Thomas's day for the succeeding year; but the former members may be, and for the most part are, rechosen. As the extent of the several wards differs very materially, so does the number, but not in exact proportion, of their representatives in the court of common council. The wards of Bassishaw and Lime Street have four each; Portsoken has five; Aldgate, Coleman Street, Cornhill, and Queenhithe, have six each; Aldersgate, Candlewick, Cordwainers, Dowgate, and Walbrook, have eight each; Vintry has nine; Broad Street, Castle-Baynard, Billingsgate, and Langbourn, have ten each; Bread Street, Cheap, and Tower, have twelve each; Bishopsgate has fourteen; Bridge Within, fifteen; Cripplegate and Farringdon Without, sixteen; and Farringdon Within, seventeen. The ward of Bridge Without can elect none, now that it has no inhabitants. Thus the whole number is two hundred and forty, with which are combined the twenty-six aldermen, making a deliberative assembly of two hundred and sixty-six members, of which the Lord Mayor is always president. They meet in a commodious apartment at Guildhall, where the aldermen have an elevated row of seats at one end; but their votes are counted with those of the common council, who are seated on the floor. The proceedings of this assembly are conducted with regularity, the business of each day being announced to the members by printed notices. Order is maintained by the power of the Lord Mayor, who, if the debate should become intemperate, can, of his own will, close the sitting, by ordering the mace to be removed. The law-officers of the corporation, the Recorder and Common Sergeant, have seats in the court, but no votes, though they mingle in the proceedings, as far as these are connected with legal subjects.

Besides these bodies, two important offices are filled by persons who may or may not be members of the corporation. They are the two sheriffs, who are the executive officers, not only of the city of London, but of the county of Middlesex. To them all writs are directed, and they have the custody of all prisoners, and the painful duty of superintending the execution of all penal laws. It is an honourable office, but an expensive one, unless (which is said to be no uncommon practice of late) the profits of the office of under sheriff are divided between that officer and the high sheriff, who appoints him. The sheriffs are chosen exclusively by the livery, from amongst the freemen. It is customary, on a fixed festival, for the Lord Mayor to drink to the health of a number of gentlemen, which is supposed to be a recommendation of them to the office of sheriff, and such persons frequently compound by a sum of money for not being called upon to serve it. It is not, however, requisite that the health of a person should be drank in this way, as any liveryman, without notice, may propose a sheriff, and he may be chosen, by having a party of his supporters collected in the Guildhall on the day of election, when very few persons attend, if no previous expectation of a contest exists. In this way improper persons have sometimes been chosen, who would not have been elected, if any opposition, followed by a poll, had been previously arranged. In such cases, the character of the other sheriff, and the ancient practice of the city, counteract any bad influence or effect which might arise from such an appointment.

The principal legal officer of the corporation is the Recorder, commonly a barrister of eminence. He is chosen by the court of aldermen alone, and for life. He had a salary of L.2500, and besides, might practise as an advocate at the assizes in the counties; but recently, on account of the increase of business, by the act including parts of Kent, Surrey, and Essex within the city criminal court, the salary has been increased to L.3500, and he is not now allowed to practise as an advocate. Next to him is the common serjeant, who is also a barrister. He is chosen by the common council, and has a salary of L.1500 per annum. Both of these officers sit as judges in the trial of criminal offences committed either within the city of London, or the county of Middlesex, or in those parts of Surrey, Kent, and Essex, which, by the law, have been brought within the limits of the jurisdiction of the court held in the Old Bailey. The chamberlain is an officer of high dignity and ample emolument. He is chosen by the livery at large, and only for one year, but is most commonly rechosen each year, and in regard to long practice, it may be considered as an office for life. He has the care of the money of the corporation, for which he gives sufficient security. All freemen are admitted by him to their freedom upon taking the prescribed oaths; and he has the settlement of all disputes between masters and apprentices. Besides these offices are those of the city remembrancer, the city solicitor, the town-clerk, and the city comptroller, which are important and lucrative, and many inferior officers, most of whom, as vacancies occur, are chosen by the court of common council by ballot.

The dignity and power of the first city officer, the Lord Mayor, is very great. He becomes, when sworn in, the king's representative in the civil government of the city; the chief commissioner of the lieutenancy; perpetual coroner and escheator within the city and liberties of the city and borough of Southwark; chief justice of oyer and terminer, and gaol delivery of Newgate; judge of the courts of Wardmote at the election of aldermen; conservator of the rivers Thames and Medway; chief commissioner in all affairs relating to the river Lea; and chief butler to the king at the coronation, for which, as a fee, he is entitled to a gold cup, with a cover and a ewer of gold.

The office is one of the most constant attendance, and such are the restraints of its duties during the year, that whoever undertakes it, usually arranges his commercial affairs so as to be able to withdraw his attention from them altogether, and devote his whole time to the public service. A salary, in some measure appropriate to the dignity of the office, is annually allowed by the corporation, amounting to L.8000, besides the use of the magnificent mansion-house as a residence, and the splendid furniture and carriages which have been provided. In the case of liberal and hospitable Lord Mayors this sum has been considerably below the actual expenditure, but with some it has been found sufficient, and a few have been so parsimonious, that they have not nearly expended the amount voted for the support of the office.

One of the greatest occasions of expense consists in the annual procession by land and water, on what is called the

Lord Mayor's Day, the 9th of November, when he enters nto office. On that occasion the new Lord Mayor meets he aldermen, sheriffs, recorder, and other great officers, t an early hour at the Guildhall, whence, in the state car-iage, attended by them in their respective carriages, he proceeds to London Bridge, where they embark in the city tate barge, and, accompanied by the barges of the city companies, proceed up the river, and land at Westminster Bridge. The party walk to Westminster Hall, where his Lordship, after some ancient ceremonies, takes the pre-cribed oaths before the Barons of the Exchequer. He hen passes with the recorder to each of the courts in the hall, and invites the several judges to dinner on that day, when he again embarks, and the procession descends the iver to Blackfriars Bridge and there lands. From thence his Lordship is preceded by the artillery company, next o which march the company of which he is a member, and hen the other city companies in their regular order, with heir distinguishing banners and bands of music; amongst he rest, the armourers have usually persons on horseback, completely equipped in various kinds of ancient armour. To these succeed the domestics and servants of the Lord Mayor, and then the state coach, finely ornamented with abundance of gilding, and so large as to contain between he seats two stools, on one of which, facing the door, sits he sword-bearer with the sword of state, and on the other he mace-bearer carrying the city mace. The train is clos-ed by the carriages of the retired Lord Mayor, of the alder-man, the recorder, the sheriffs, the chamberlain, the common erjeant, the town-clerk, and other great officers, and the procession returns to the Guildhall. This annual proces-ion excites great interest both on land and water, and ex-hibits an extraordinary display of municipal splendour. The day closes at Guildhall by an entertainment of appropriate magnificence, at which it is common to see members of the oyal family, the most distinguished public characters, and often the ambassadors of foreign courts. About a thousand individuals take their seats at this dinner, to which they are admitted by tickets from the Lord Mayor and Sheriffs, who, in fixed proportions, bear their share of the expense, which generally amounts to about L. 3000.

Under the corporation of London criminal justice is extensively administered. At the sessions the Lord Mayor is supposed to preside even when the judges are trying prisoners, and the presence of at least one alderman is deemed necessary. The Lord Mayor sits daily at the Mansion-house for the examination of offenders, and the committal of prisoners for trial; and an alderman, on fixed days in each week, attends for the same purpose at Guildhall, the aldermen being all *ex officio* justices of the peace. There are inferior courts for the recovery of small debts, and some for the determination of civil causes, such as the Lord Mayor's Court, the Court of Hustings, the Sheriffs' courts, and some others.

The management of the great estates and other property belonging to the corporation require much attention. The care devolves on the court of common council, which, for this purpose, is divided into committees, that regulate whatever relates to the several divisions into which the property is classed, but under the ultimate direction of the general court. Each of these committees has one or more aldermen nominated as members of it, and the other members are appointed by the court in regular rotation. The committees which have the most business to transact are those of the Irish estates, of the city lands, and of the bridge estates; but there are several others, some of them permanent, and others only appointed as occasions require their formation.

This sketch of the corporation of London might have been fuller and more minute if the report of the Commissioners of Municipal Corporation inquiry had been printed. It may be proper, however, to notice the general apprehension, that all corporate bodies will, in a few years, present a different appearance from that which they have hitherto done; and that London, though the last, will certainly undergo a renovation, which may render any greater extension of this branch of our subject an unnecessary and uninteresting enlargement.

London, *New*, a city and port of entry in the United States of North America, in New London county, Connecticut. It is situated on the western bank of the river Thames, three miles from its mouth, and thirteen miles south of Norwich. The town is irregularly laid out, but has convenient public buildings, and churches for Congregationalists, Episcopalians, Baptists, and Methodists. New London harbour is the best in the state; and packets and steam-boats ply regularly between the port and New York. It is defended by Fort Trumbull on the west side of the river, and by Fort Griswold on the east side. There is likewise a lighthouse, which has been erected on a point projecting pretty far into the sound. A considerable commerce is carried on, both in the coasting trade with the southern states, and in foreign trade with the West Indies. The population amounted in 1821 to 3330, and in 1831 to 4356. Long. 72. 9. W. Lat. 41. 22. N.

LONDONDERRY, a maritime county in the province of Ulster, in Ireland, is bounded on the north by the Atlantic, on the east by the county of Down, on the south by that of Tyrone, and on the west by Donegal and Lough Foyle. The area is imperfectly triangular. Its greatest length is from the point of Magilligan, at the entrance of Lough Foyle, to Cookstown, a distance of fifty-two miles; its greatest breadth, from the western point of the liberties of Londonderry to Vow Ferry on the Bann, is forty-four miles. It extends over a surface of 518,270 acres, of which 372,667 are cultivable land, 136,038 bog or unprofitable mountain, and 9565 are under water.

According to Ptolemy, who is followed by Whitaker, the tribe of the Robogdii were located here. Afterwards it was the territory of the O'Canes, or O'Cathans, feudatories of the great O'Neil family. After the confiscation of this latter chieftain's princely estate, in consequence of his abrupt flight into Spain at the commencement of the reign of James I., this county, which formed part of its northern portion, was parcelled out amongst twelve companies of London tradesmen, by whom, or their representatives, the greater part of it is still held. Their names are the drapers, salters, vintners, mercers, ironmongers, merchant tailors, cloth-workers, haberdashers, fishmongers, grocers, goldsmiths, and skinners, forming together a body or corporation called the Irish Society. It is now divided into the baronies of Coleraine, Kenaught, Loughinsholin, and Tyrkerrin, together with the liberties of Londonderry and Coleraine, which have separate jurisdictions. In this arrangement it is remarkable that each of the two latter divisions is situated beyond what may be deemed the natural boundaries of the county, the former lying west of the river Foyle, and the latter east of the river Bann. These greater divisions are subdivided into thirty-five parishes, twenty-seven of which are in the diocese of Derry, five in that of Armagh, and three in that of Connor.

The diocese of Derry is much larger, both as to number of parishes and extent of surface, than the county, comprehending, besides the twenty-seven parishes above named as being within the civil boundary, ten in Donegal, eleven in Tyrone, and part of a parish in Antrim. By a curious anomaly, the ecclesiastical jurisdiction of the parishes in the liberties of Coleraine belongs to the Bishop of Down and Connor. The seat of the see is in the city of Derry, where is the cathedral, a building in the Gothic style, erected in 1633. The chapter consists of a dean, an archdeacon, and three prebendaries.

The neighbourhood of the great Western Ocean, and the height of the mountain ranges, which either intersect or skirt the county, may account for the fall of a considerable quantity of rain; yet the popular notion of the peculiar wetness of the climate here arises more from the frequency of showers than from the amount of water discharged by them. The maximum annual quantity of rain, during a period of seven years, did not amount to thirty-five inches, the minimum twenty-five inches. The average of rain taken during a period of seven years here and at Keswick in Cumberland, and Kendal in Westmoreland, exhibits the following results:

	Maximum.	Minimum.	Average.
Londonderry	35	26	31 inches.
Keswick or Kendal	84	34	68

Neither does it appear that the north-west wind, so prevalent here, however unfavourable to vegetable, is at all injurious to animal life. On the contrary, the most remarkable instances of longevity have been found on the coast, and in the peninsula of Magilligan. Several instances have occurred of the extension of human life to ninety and even to a hundred and ten years.

The surface of the county presents an appearance of valleys separated from each other by ridges of rugged, but not very elevated mountains, and expanding, as they approach the coast, into alluvial plains. The most elevated of the mountains are, Sawel, 2236 feet high; Slieve Gallen, 1730 feet; Cairntogher, 1521 feet; Donald's Hill, 1310 feet; Benyevenagh, 1262 feet; and Legavannon, 1290 feet.

The principal river is the Roe, which, receiving as it flows in a northerly direction the tributary streams of the Owenbeg, Owenmore, Gelvan, Castle, and Curley, discharges itself into Lough Foyle; it is subject to sudden and violent floods. The mud deposited near its mouth forms shifting banks, which prevent it from being a useful port for small craft, otherwise the channel is deep enough to be navigated for two miles by flat-bottomed barges. The Faghan rises in the south, and discharges itself into Lough Foyle near Culmore. The Moyola takes a south-eastern course, and falls into Lough Neagh. A small portion only of the fine navigable river Foyle belongs to the county, passing in its course through the liberties of Londonderry. It is navigable for vessels of large burden as far as the city of Londonderry, and thence to Lifford in Donegal for lighters of twenty tons. The Bann, from Lough Neagh, forms the eastern boundary until it approaches Coleraine, where it separates the barony from the liberties of the town. The navigation of this river is impeded by shoals, which form a dangerous bar.

The valleys formed by these rivers, and their subordinate branches, are called *slacks*. That of the Faghan presents some scenery that is peculiarly picturesque, as also does that called the slack of Feeny, a pass which connects the valleys of the Faghan and the Roe. Several glens discharge their streams into this slack; the most beautiful is that of Fin-Glen. On the western side of the ridge of Benyevenagh there is a very uncommon surface called a shaking quag, and also named the Gray Lough. It spreads over many acres. Cattle can pass freely through it in summer, yet at every step the soil yields to the pressure, communicating an undulating motion all around. The surface is broken in every direction by pits full of water of unfathomable depth, and all invariably rectangular parallelograms, very much resembling tan-pits. The quag is surrounded by declivities on almost every side, and therefore it is difficult to account for the cause of its retaining such a quantity of water without any apparent supply. The structure of its margin, formed of stratified substances covered with turf, may, however, account for the retention of the water. There may have been a large lake here, which, by the interlacing roots of the aquatic plants, is now covered with a kind of network that supports the foot, except in places where the workings of the surface produce a fissure. But the cause of this extraordinary regularity of shape in the pits thus formed still remains without satisfactory explanation. The only lake is Lough Finn, situated in the confines of Tyrone; it is of very inconsiderable dimensions. Lough Neagh touches the county in a small portion of its south-eastern boundary. The small port of Ballyronan, in the north-west angle of the lough, affords accommodation for sloops of sixty tons to load and unload. The fine inlet of the Atlantic called Lough Foyle forms the principal part of the western boundary. Having a narrow entrance, but with ten fathoms of water, between Culmore Fort and Magilligan Point, it expands itself into a gulf of fifteen miles in length and seven in breadth, with a channel fourteen fathoms deep at low water, but of difficult navigation from its great narrowness.

The soil in the northern part, along the sea-coast, is a stiff and reddish clay, interspersed with knolls of basalt, and resting on a substratum of white lime, which occasionally shows itself on the surface. Near the mouth of the Roe is an extensive tract of a marly nature, formed of layers of ouze and shells alternating to a depth of several feet. Fossil shells are frequently found in the ditches. The lands lying between the loamy soil in the low grounds and the higher wastes are either of a blue clay with fragments of quartz, slate, and a shallow covering of peat moss, or a shingle of slate interspersed with red ochreous sand or with gravel and loam. Above the lime is the region of the basalt, and the soil is thenceforth without clay, being merely an oxide of the softer parts of this ironstone, having neither cohesion nor strength, and producing little but potatoes and straw. The country people significantly call it draff land. Yet its summits are admirable as sheep walks; for, how high soever the elevation of a basaltic mountain may be, if the immediate substratum be of the fossil known by the name of zeolite trap, the soil is fertile and the herbage sweet, presenting an elegant carpeting of shamrock, daisy, butter-cup, and plantain, which is eagerly browsed on by sheep.

The valley of the Roe divides the county into two districts, totally different in respect to their geological character. On the west lies the territory of schist, on the east that of basalt, each accompanied with its peculiar fossil organization. The prevalent species of schist is a kind of flag-rock or schistose mica, next to which in quantity is the laminated schist or flag, the dip of which is generally north-west. The great mountain of Sawel is composed of several varieties of this rock, surmounted towards the summit by amorphous whinstone, interspersed with blocks of quartz. Slieve Gallen is also a mass of basalt, resting upon a bed of granite, which emerges from beneath in various places. Limestone may be found everywhere, from the sea to Benbradagh. The most remarkable cavern on the coast is in the white limestone; it is very appropriately called the Robber's Cave, having at one time been the asylum of a formidable banditti. A species of blue limestone has been used for various architectural purposes. Sandstone is universally found below the basalt, and is occasionally intermingled with schist. A species of it, of a bright tawny colour, not unlike to that of the Portland stone, is raised in large quantities near Dungiven. Many of the principal buildings are constructed of it. Coal has not yet been discovered in any quantities deserving of notice. Iron is found in great abundance, either in an ochreous state, or mixed with manganese, when it is known by the name of bog ore or woad. The base of Sawel is a mass of martial pyrites mingled with schist. To the abundance of this metal in the peat moss is to be attributed the red colour of the ashes, which are so heavy as to keep in heaps even in a breeze of wind. The metal was formerly smelted, but the operation has been ultimately relinquished as an unprofitable speculation. Copper and lead, in small veins, have been discovered. Boate states that pure gold had been found in a rivulet which discharges itself into Lough Neagh; but the fact has not been substantiated by subsequent discoveries, further than that some specimens of quartz have been observed to contain thin laminæ of that metal. Quartz and flint are common in all parts. The flint sometimes exhibits marine impressions, the quartz never. As to crystals, they are of great variety. Zeolite, in rose-cut surfaces, in points, and in thistledown, all beautiful, are common in basalt. The rock-crystals are found exclusively in the schistose regions. They are harder than those found in Kerry. In shape they are truncated prisms of six sides and six facets, and weigh from two to twelve ounces. In all the mountains composed of pyritic schist the streamlets show strong indications of iron, to such a degree, indeed, that in some places the water is not fit for drinking.

The population has increased progressively from the earliest period at which any probable estimate of its amount was made, as appears by the statements from the following authorities:—

Year.	Authority.	Number of Souls.
1760	De Burgho	46,182
1792	Beaufort	125,000
1813	Parliamentary census	186,181
1821	Ditto	193,869
1831	Ditto	222,116

The last of these estimates gives an average of one inhabitant to every two and a third acres throughout the county, or to every one and a fifth acre of cultivable land. The county was represented in the imperial parliament by eight members, two for the county at large, and two for each of the boroughs of Londonderry, Coleraine, and Newtown-Limavady. The act of union reduced the number of borough members to one each for Londonderry and Coleraine. This arrangement still continues.

The state of public education, according to the official returns in 1821 and 1824–26, is as follows:

Year.	Boys.	Girls.	Sex not ascertained.	Total.
1821,	4610	2111	...	6,721
1824–6,	5836	7925	135	13,890

In religious persuasion, the numbers stated in the latter of these returns stand thus:—Of the Established Church 2446, Roman Catholics 4494, Dissenters 6695, besides 255 whose religious tenets were not ascertained. According to the same return, the number of schools was 380, out of which, forty-nine, affording instruction to 3119 children, were supported by grants of public money; fifty-three, affording instruction to 2748 children, were maintained by the voluntary contributions of individuals or societies; whilst the remaining 278 schools, in which 8023 children were educated, depended wholly on the fees of the pupils. The diocesan school in the city affords the means of liberal education to the sons of the gentry. It is an extensive and well-conducted establishment. The endowment consists of a salary from the London Society, and a subscription from the bishop and beneficed clergy. A mercantile school in Coleraine has also been endowed by the same society.

The treatment of arable ground differs little from that generally practised throughout the province. The principal crops are barley, oats, and potatoes; the implements the Scotch and Irish ploughs; the manures sea-weed, and composts of which it forms a part, near the coast, and lime and turf-mould in the interior. In Magilligan, the mossy sands are alternately ploughed and laid up in meadow. The fiorin grass springs up luxuriantly here. Amongst the more uncommon species of grasses may be mentioned the *Parnassia palustris*, commonly called crottel, in Irish croutuil; when manufactured, it produces the litmus, turnsol-blue or archil. Extensive dairies are uncommon; the care of milk and butter forms generally a part of the domestic economy of the working farmer. Sheep are mostly brought in at fairs from other districts. There are no herds of goats in the mountains, but individually they are found in many of the habitations of the cottiers. Magilligan contains a very large rabbit-warren, extending over 1500 acres. The annual number of skins sent out of it is 2000; they are sold by auction to the Dublin hatters. The poultry are large. Geese are both large and abundant. They fatten in summer on the vetches and tares which abound in the bottoms, in autumn on the stubble, and in winter on the potato-ridge. Wild and sea fowl are abundant. The county was once remarkable for the quantity of honey it produced; latterly the produce has decreased.

The linen manufacture is the staple here, and contributes greatly to the comfortable support of the population. The yarn and linen are generally of a coarser staple than in the neighbouring county of Antrim. Sacking is made of the tow-yarn. Potteries, in which the coarser kinds of earthenware are manufactured, are carried on in some places. There are several large distilleries and breweries, and some salt-works. One of the most productive salmon-fisheries in Ireland is on the Bann, near Coleraine. Lampreys are caught at low water at the mouth of the same river. Eels are plentiful in all the streams. The sea furnishes most kinds of fish taken upon other parts of the coast. The sturgeon and sun-fish have been caught in Lough Foyle. An unique specimen of the opah or king-fish was thrown on shore upon the sands of Magilligan. Whales of various species have also been taken on the coast. The seal, porpoise, and grampus are frequent. A species of the pearl mussel has been found in the rivulet which flows through Claady into the Bann.

The residences of the nobility, and landed proprietors of large fortune, are elegant, and in some instances magnificent. Two mansions, erected by the Earl of Bristol, who had been Bishop of Derry, the one at Downhill, the other at Ballyscullion, were constructed in a style of Grecian architecture. The latter has been suffered to fall into ruin. The habitations of the farmers in some of the richest districts, where stone is scarce, are built of clay, and almost universally covered with thatch; presenting, however, with few exceptions, an appearance of comfort and good order. In all cases, they are built and kept in repair by the tenant. In the houses on the Antrim side of the Bann, the fire-place is advanced some feet from the gable-wall, so that the family can nearly sit round it. It does not appear that the nuisance of smoke is so much felt in houses thus constructed as in those in other parts of the country, in which its smell, and its action upon the eyes, are very offensive to strangers. In the districts where lime is plentiful, the outside of the cabin is whitewashed, and sometimes roughcast; whence, amongst the wildest mountains, scenes of domestic neatness often unexpectedly arrest the eye. Coal is little burned in the country parts. In the open and more fertile districts, which are consequently most thickly peopled, the peat mosses are nearly exhausted. In such situations, when the turf can no longer be cut, it is collected into heaps of wet mire, and moulded by the hand. It is then called baked turf, and makes bad fuel. Providence seems to have compensated the dreary exposure of the mountain districts, by affording them plenty of turbary, which has allured a crowded population to every arable spot, however remote or dreary, where turf is to be had in plenty. The article, when prepared for fuel, is carried down to the lowlands on slide cars, through winding ruts, which present to the inexperienced eye insuperable difficulties in the way of its transit. Bog fir is used amongst the wealthier classes as a good substitute for cannel coal. The cottier cuts it up into laths, called splits, not thicker than the blade of a knife. These are used instead of candles, and serve to give light enough to guide the operations of humble domestic industry during the long winter evenings.

The manners of the common people exhibit much kindness and courtesy. A stranger, on visiting the cabin, is offered a chair brought from the inner apartment. A remarkable tone of piety pervades their usual conversation. Few make a promise for the future without adding, "with the help of God," or some other phrase of similar import. They talk much of "the second means," and, through an over confidence in providential interference, often disregard human aids in cases of sickness. Superstitious notions are prevalent, some of them in common with those in other parts of Ulster, others more peculiar to themselves. When the cottier's cow is supposed to be "elf-shot," recourse is not had to animal medicines, but salt and water poured on three halfpence and a petrified sea-urchin called "the fairy's bullet," and common in limestone, is deemed an infallible remedy. The weasel is accounted "sawncy," that is, lucky, about the house. If a cow dies in calving, her flesh must be eaten by "Christians," and not given to the dogs. There is an almost insurmountable objection to taking an oath according to the usual form. It is most prevalent amongst the seceders, to whose prejudices in this respect the legislature has wisely yielded, by accepting their testimony on asseveration with uplifted hand. At weddings, amongst the Scotch part of the population, the bridegroom and his friends vie with each other in being the first to gallop to the house of the bride. During the race they are greeted with shots from guns and pistols in every village they pass through. A bowl of broth, called "brose," stands ready prepared at the winning-post, as the reward for the victor in the race. The forms of an Irish wedding in the mountain districts are very different. However suitable the match may be to the wishes of all parties, it is considered as but a sorry exploit unless the bride be run away with. After a few days the parties return, and a liberal carouse, to which every well-wisher of either party is expected to contribute, forms the celebration of a kind of second nuptial.

The most remarkable relic of ancient fortification is the Giant's Sconce, situated in the pass between Drumbo and Largantea. It was formed on an isolated knoll of basalt, difficult of access on all sides but the north-east, where art has supplied the deficiency by a wall of massive masonry. The interior was hollowed, as if for a receptacle for men and stores; whilst a covered way, admitting only one person in a stooping posture to pass at a time, surrounded the whole. Several cromleachs are still in existence, some of them surrounded by a circle of upright pillars, somewhat like Stonehenge. The most remarkable is that at Slacht Manus. Cairns are too numerous to admit of special notice. To the present time they are kept up, if not enlarged, by the custom of travellers adding a stone to them as they pass. Danish ditches are sometimes dug up. Sepulchral pillars are numerous, and one peculiarly remarkable stands near Dungiven. Artificial caverns, evidently constructed for the concealment of men and property, are frequently discovered. They are rudely built of stone, without cement; and flags or long stones form the roof. They consist of narrow galleries, some at right angles with the main entrance, others parallel to it. The entrance is usually concealed by a rock or grassy sod. Moats, the body of which seems to have been formed of the earth thrown out of the foss, have been found. These enclosures are too low for safety or strength, and so small as not to contain more than thirty persons. Coins, antique pins, rings, and forks, were found in one of them. Castles of acknowledged Irish erection are few. That of Carrickreagh is looked upon as amongst the most ancient. Near Ballyaghran was another. Both are said to have been residences of the family of the M'Quillans. Pieces of pit-coal, found in the cement of the walls, lead to the opinion that the operations of miners were practised in those remote ages. Some of the castellated mansions of the first English settlers, with their bawns, are still in a state of preservation; as at Killolod, Dungiven, Salterstown, and Muff.

The most ancient monastic building is the abbey of Derry, founded by Columbkill in the sixth century. The present cathedral stands on its site. At Coleraine were two monasteries, one of Dominicans, the other of regular canons. At Camus, on the Bann, was a very celebrated monastic structure, attributed to St Comgal. The only remains of it at present existing are the fort, with a pillar curiously carved. The remains of the abbey of Dungiven are the most interesting in the county. It was the burial-place of the O'Cahans or O'Kanes, several of whose tombs have resisted the attacks of time. The principal monument is that of one of the chieftains, named Cooey-na-gal. There is a tower at the north-west side of the building, and a sepulchral pillar placed on an artificial mount. A smaller tumulus in the vicinity, when opened, was found to contain an urn of earthenware with bones. The urn was surrounded with white stones. Other tumuli, when examined, exhibit similar results.

The city of Londonderry is situated at the western side of the river Foyle, near to its junction with the lough, spreading itself over the summit and sides of a hill, which here projects into the river, and which was once covered with oak trees, whence the place derived the name of Derry Calgach, "the eminence covered with oaks," which it still partially retains. Its monastery first drew inhabitants thither. The town was entirely ecclesiastical, consisting almost exclusively of churches and the dwellings of the clergy and their dependents. The English government, after having been baffled in several attempts to plant a garrison here during the war against the Earl of Tyrone, at length succeeded, in 1600, in gaining possession of the place, and securing it against any efforts of the Irish to dislodge them. It was surrounded with a substantial wall, strengthened with bastions, and had four main streets diverging at right angles from a point on the summit of the hill, now called the Diamond, to a gate at the other extremity of each. The strength of these fortifications was tested in the subsequent wars of 1642 and 1688, in each of which the town maintained a successful stand against its besiegers. After a lapse of more than two centuries, the walls still retain, in most parts, their original form and character. The external ditch, indeed, has disappeared. The gates have been rebuilt in a more elegant style of architecture, and two new ones have been added. One bastion has been removed to make way for a butter-market, and another has been appropriated as the site of a pillar commemorative of the military services of the Reverend George Walker during the memorable siege of 1688. In other respects the walls still remain unaltered, now forming the ornament, as they were once the protection, of the city. They are the favourite walk of the inhabitants, frequented by the beauty and fashion of the city, and commanding, at various points, interesting and extended views of a wooded and watered landscape. The cathedral stands within the walls, in the southern part of the city. It consists of a nave, divided into a central and lateral aisle, separated by pointed arches. The chapel of ease is a plain rectangular structure, of small dimensions. A free church, for the use of the poor, was opened in 1830, at the expense of the late bishop. There are four meeting-houses, one for the Presbyterian or Scotch church, a second for the Seceders, a third for the Covenanters, and a fourth for the Independents. There are also two Methodist chapels, and a Roman Catholic chapel capable of accommodating 2000 persons. The diocesan school is a simple but handsome stone edifice, consisting of a central pavilion and two wings. It was erected by grants from the London companies, and a large contribution from the bishop. Near to it is the parish or poor school, with accommodations for children of both sexes. The corporation hall stands in the centre of the Diamond. It is surrounded by a colonnade, with embattlements; and the same kind of military ornament surrounds its roof. The court-house exhibits much architectural beauty. The other more remarkable public buildings are, the lunatic asylum, the infirmary and fever hospital, the gaol, the custom-house, the linen-hall, the barrack, and the magazine. The bridge is the peculiar boast of Derry. It is built of wood, and extends in length 1068 feet, by a breadth of forty. A turning bridge, near the centre, admits a free navigation to vessels going up the river. Walker's Testimonial is a pillar of the Roman Doric order, surmounted by a statue of that celebrated individual. Its height is ninety feet. The markets are good, and well provided with accommodation for buyers and sellers.

The municipal jurisdiction extends over a space of three miles in every direction from the centre of the city. The government is vested in a mayor, twelve aldermen, two sheriffs, and twenty-four burgesses. The income of the corporation arises from tolls on the bridges, tolls on the market, rents of land and shambles, and tonnage and quayage.

The progress of commerce may be estimated from the custom-house receipts, which for eight years were as follow:

Years.	L.	Years.	L.
1827	14,462	1831	73,512
1828	78,595	1832	74,377
1829	74,561	1833	74,049
1830	74,856	1834	72,871

The shipping of the port of Derry in 1760 consisted of sixty-seven sail, of from thirty to three hundred and fifty tons. The following table exhibits the vessels employed in the foreign and coasting trade for eight years.

Years.	Foreign.				Coastwise.			
	Inwards.		Outwards.		Inwards.		Outwards.	
	No.	Tons.	No.	Tons.	No.	Tons.	No.	Tons.
1826	59	10,450	21	5559	422	32,632	307	20,498
1827	59	9,961	24	6132	481	42,165	393	34,233
1828	39	6,686	11	2553	628	50,243	521	45,083
1829	48	7,537	14	3865	574	48,912	508	43,347
1830	64	10,989	13	2689	612	51,088	515	42,986
1831	37	6,286	10	1989	694	58,955	547	44,351
1832	50	10,310	16	4321	637	62,032	555	50,303
1833	57	11,294	22	6845	607	63,879	540	52,952
1834	57	10,406	16	4869	649	63,726	646	62,502

Hence it appears that the increase of shipping and commerce has been wholly in the cross-channel trade. Of the vessels included in that part of the table, the following were steamers:—

Year.	No.	Ton.	Year.	No.	Ton.	Year.	No.	Ton.
1829,	1	136	1831,	2	300	1833,	3	516
1830,	1	136	1832,	3	516	1834,	5	741

The population of the city at different periods has been estimated as follows:—

Year.	Authority.	Number of Souls.
1618	Pynnar	612
1690	Archbishop King	700
1792	Beaufort	10,000
1814	Irish Society	14,087
1821	Parliamentary return	9,313
1831	Ditto	10,130

Coleraine, the second town in importance, is situated on the eastern or Antrim side of the Bann, near its mouth. Like Londonderry, it owes its existence chiefly to the fostering care of the London companies. Some of the houses built of frame or cage-work in the time of Elizabeth and James I. are yet in preservation. According to the fashion of those days, they have pent-ways or piazzas. The population at present amounts to 5752 souls. The other more remarkable towns are, Newtown-Limavady, Magherafelt, Killreagh, Dungiven, Garvagh, Maghera, Moneymore, Tubbermore, Castledawson, and Bellaghy.

LONG, an epithet applied to whatever exceeds the usual standard of length in its kind.

Long-Boat, the largest and strongest boat belonging to any ship. It is principally employed in carrying great burdens, as anchors, cables, ballast, and the like.

Long-Benton, a large parish of Castle-ward, in the county of Northumberland, 281 miles from London. The population amounted in 1801 to 3355, in 1811 to 4358, in 1821 to 5547, and in 1831 to 6613.

Long Island, an island of America, belonging to the state of New York, about 120 miles in length and from ten to twenty in breadth. It extends along the coast in the form of a crescent, and is separated from the mainland by a bay which communicates with the sea at both ends, called Long Island Sound. The southern and western parts are generally of a light soil, which, when well manured, produces excellent crops of grain, especially Indian corn. Towards the east and north the land becomes hilly, and the soil much stronger, and a large quantity of wood is there raised to supply the city of New York. A considerable portion has been laid out in orchards and nurseries, and, from the general high state of cultivation in this island, it has sometimes been called the garden of the United States. It is divided into three counties, King's, Queen's, and Suffolk, and possesses many thriving towns and villages, the principal of which are Brooklyn, Jamaica, Sag Harbour, Flatbush, Flushing, Satauket, and Huntington. Brooklyn, the chief town, is a large and thriving place, situated opposite the city of New York, with which a regular communication is kept up by means of steam. It is a compact and handsome town, having several public buildings, various manufactories, a bank, and an extensive trade. To the north-east is the United States navy-yard. The population of the town in 1830 was 15,394, and that of the whole island 69,775.

Long Island, a small island, about forty miles in circumference, situated off the coast of Papua, between the ocean and Mysore island, and almost wholly unknown in the interior.

Long, *Roger*, master of Pembroke Hall in Cambridge, Lowndes professor of astronomy in that university, rector of Cherryhinton in Huntingdonshire, and of Bradwell *juxta mare* in Essex, was author of a treatise of astronomy, and the inventor of a curious astronomical machine. The latter is thus described by himself: "I have, in a room lately built in Pembroke Hall, erected a sphere of eighteen feet diameter, wherein above thirty persons may sit conveniently. The entrance into it is over the south pole by six steps; the frame of the sphere consists of a number of iron meridians, not complete semicircles, the northern ends of which are screwed to a large round plate of brass, with a hole in the centre of it. Through this hole, from a beam in the ceiling, comes the north pole, a round iron rod about three inches long, and supports the upper parts of the sphere to its proper elevation for the latitude of Cambridge. The lower part of the sphere, so much of it as is invisible in England, is cut off; and the lower or southern ends of the meridians, or truncated semicircles, terminate on and are screwed down to a strong circle of oak, of about thirteen feet diameter, which, when the sphere is put into motion, runs upon large rollers of lignum-vitæ, in the manner that the tops of some windmills are made to turn round. Upon the iron meridians is fixed a zodiac of tin painted blue, whereon the ecliptic and heliocentric orbits of the planets are drawn, and the constellations and stars traced. When it is made use of, a planetarium will be placed in the middle thereof. The whole, with the floor, is well supported by a frame of large timber." Dr Long published a Commencement Sermon in 1728, and an answer to Dr Galley's pamphlet on Greek Accents; and he died on the 16th of December 1770, at the age of ninety-one.

LONGEVITY, the same as length of life. From the different longevities of men in the beginning of the world, after the Flood, and in subsequent ages, Mr Derham deduces an argument for the interposition of a divine Providence. Immediately after the creation, when the world was to be peopled by one man and one woman, the ordinary age was nine hundred and upwards. Immediately after the Deluge, when there were only three persons to stock the world, their age was cut shorter, and none of those patriarchs excepting Shem arrived at five hundred. In the second century we find none who reached two hundred and forty, and in the third none but Terah who arrived at two hundred years; the world, at least a part of it, by that time being so well peopled that they had built cities, and cantoned themselves out into distinct nations. By degrees, as the number of people increased, their *longevity* diminished, until at length it came down to seventy or eighty years. That the common duration of man's life has been the same in all ages since the above period, is plain both from sacred and profane history. Plato lived until he was eighty-one, and was accounted an old man; and the instances of longevity produced by Pliny (lib. vii. c. 48) as very extraordinary may most of them be matched in modern histories. In the following tables are collected into one point of view the most memorable instances of long-lived persons of whose respective ages we have any authentic records.

Longford.

Names of the Persons.	Age.	Places of Abode.	When they died.
Thomas Parre	152	Shropshire	Died November 16, 1635. Phil. Trans. No. 44.
Henry Jenkins	169	Yorkshire	Died December 8, 1670. Phil. Trans. No. 221.
Robert Montgomery	126	Ditto	Died in .... 1670.
James Sands	140	Staffordshire	Ditto, Fuller's Worthies, p. 47.
His Wife	120	Ditto	
Countess of Desmond	140	Ireland	Raleigh's Hist. p. 166.
.... Ecleston	143	Ditto	Died .... 1691.
J. Sagar	112	Lancashire	.... 1668.
Simon Sack	141	Trionia	...... May 30, 1764.
Colonel Thomas Winslow	146	Ireland	...... August 26, 1766.
Francis Consist	150	Yorkshire	...... January ... 1768.
Christ. J. Drakenberg	146	Norway	...... June 24, 1770.
Francis Bons	121	France	...... February 6, 1769.
James Bowels	152	Killingworth	...... August 15, 1656.
John Tice	125	Worcestershire	...... March 1774.
John Mount	136	Scotland	...... February 27, 1766.
A. Goldsmith	140	France	...... June ... 1776.
Mary Yates	128	Shropshire	.... 1776.
John Bales	126	Northampton	...... April 5, 1776.
William Ellis	130	Liverpool	...... August 16, 1780.
Janet Taylor	108	Fintray, Scotland	...... October 10, 1780.
Susannah Hilliar	100	Piddington, Northamptonshire	...... February 19, 1781.
Ann Cockbolt	105	Stoke-Bruerne, *ibid.*	...... April 5, 1775.
James Hayley	112	Middlewich, Cheshire	...... March 17, 1781.

Although longevity prevails more in certain districts than in others, yet it is by no means confined to any particular nation or climate; nor are there wanting instances of it in almost every quarter of the globe. This appears from the preceding table, as well as from that which is here subjoined.

Names of the Persons.	Age.	Places of Abode.	Where recorded.
Hippocrates, physician	104	Island of Cos	Lynche on Health, chap. iii.
Democritus, philosopher	109	Abdera	Bacon's History, 1095.
Galen, physician	140	Pergamus	Voss. Inst. lib. iii.
Albuna, Marc	150	Ethiopia	Hakewell's Ap. lib. i.
Dumitur Raduly	140	Haromszeck, Transylvania	Died January 18, 1782. General Gazetteer, April 18.
Titus Fullonius	150	Bononia	Fulgosus, lib. viii.
Abraham Paiba	142	Charlestown, South Carolina	General Gazetteer.
L. Tertulla	137	Ariminum	Fulgosus, lib. viii.
Lewis Cornaro	100	Venice	Bacon's History of Life, p. 134.
Robert Blackeney, Esq.	114	Armagh, Ireland	General Gazetteer.
Margaret Scott	125	Dalkeith, Scotland	Inscription on her tomb there.
W. Gulstone	140	Ireland	Fuller's Worthies.
J. Bright	105	Ludlow	Lynche on Health.
William Postell	120	France	Bacon's History, p. 134.
Jane Reeves	103	Essex	St James's Chron. June 14, 1781.
W. Paulet, marquis of Winchester	106	Hampshire	Baker's Chron. p. 502.
John Wilson	116	Suffolk	Gen. Gaz. October 29, 1782.
Patrick Wian	115	Lesbury, Northumberland	Plemp. Fundam. Med. § 4, c. 8.
M. Laurence	140	Orcades	Buchanan's Hist. of Scotland.
Evan Williams	145	Caermarthen work-house	General Gazetteer, October 12, 1782.
John Jacobs	121	Mount Jura	All the public prints, Jan. 1790.
Matthew Tait	123	Auchinleck, Ayrshire	Died February 19, 1792. Edin. Even. Cour. March 8, 1792.

We have seen a list of a hundred and four persons, one of whom died under a hundred and twenty years f age, and one of whom, it is said, lived to the prodigious ge of a hundred and eighty. Of these long-lived indiviuals, forty-one belonged to England, sixteen to Scotland, nd twenty-four to Ireland.

For further information on this subject, the reader is referred to the article Mortality, Law of.

LONGFORD, an inland county in the north-western extremity of the province of Leinster, in Ireland, is bounded on the north by the counties of Leitrim and Cavan, on the east and south by Westmeath, and on the west by

Longford.

Roscommon, from which it is separated by the Shannon. It is amongst the smallest counties in Ireland, and the smallest but one as to the quantity of arable land; its contents being 263,645 acres, of which 192,506 are capable of cultivation, 55,247 are unprofitable mountain or bog, and 15,892 are covered with water.

The county, according to Whitaker, was peopled by the tribe of the Scoti, who spread themselves over most of the inland regions. Afterwards, under the name of the Annaly, it became the principality of the O'Ferrals. In the reign of Elizabeth, it was made shire-ground, being one of the seven counties into which Connaught was then divided; but it was afterwards transferred to Leinster, of which it still continues to form a part. It is divided into the six baronies of Abbeyshruel, Ardagh, Granard, Longford, Moydow, and Rathcline, which are subdivided into twenty-three parishes, all in the diocese of Ardagh, except one, which is in that of Meath.

The diocese of Ardagh, which was founded in the fifth century, was in 1658 united with that of Kilmore, from which it was subsequently separated, and, after being for some time held alone, was ultimately united with the archdiocese of Tuam, to which it is still attached; but, according to the new ecclesiastical arrangements, it is to be separated from it, and united with the sees of Kilmore and Elphin. No traces of the cathedral are now in existence. All that remained of it in the middle of last century was part of a wall built of large stones, which apparently had formed a portion of a very small edifice.

By much the greater part of the surface of the county is level, but in its northern angle it rises into bleak and rugged hills of no great elevation; and some hills also protrude in various parts of the plain country. The general surface is of considerable elevation, the summit-level of the Royal Canal, which is within the county, being 290 feet above the level of the sea. The general appearance of the country, though in many parts well planted and cultivated, presents few attractions to the lover of the picturesque. The only rivers of any size are, the Camlin, which rises near Granard, and flows by the town of Longford into the Shannon near Tarmonbarry; and the Inny, which has its source in Lough Shillin, on the borders of Cavan, passes by the southern border of the county, through a fertile and well-peopled district, and discharges itself, after a winding course, into Lough Reagh, being navigable from Ballymahon. There are several lakes within the county, but none of them of great extent. The most remarkable are Lough Gawnagh in the north, Derrylough, Lough Drum, and Lough Bannow. The fine expanse of Lough Reagh, on the western side of the county, may be considered as partly belonging to it. It has in it the islets of Innisbofin, Innisclothran, and Innismacsaint. Lough Derrymacar is merely an arm of this lake. The quantity of bog is considerable. The bog, myrtle, and larch, grow freely in it. In some of the bogs are deep holes, which throw up large quantities of water; they are known by the name of swallow-holes. In 1809, part of the bog near Johnstown burst away from the main body, and moved to a considerable distance, crossing in its passage the river Camlin, the channel of which it choked up, and caused all the adjoining lands to be flooded.

The northern boundary of the great limestone field of Ireland passes through this county. The line of division is marked by the Camlin as far as Longford town, and thence proceeds by Johnstown to Lough Shillin. To the north of this line the formation is of clay-slate and greywacké. Isolated hills of sandstone show themselves at Slievegoldry and at Ballymahon, on both sides of the Inny. Indications of iron are abundant in the northern parts. Near Lough Gawnagh very rich iron ore is found, not in thin beds, as in Leitrim and Roscommon, but in solid rocks of a dark-red colour, and it breaks into small shelving prisms. Indications of coal appear in the same neighbourhood. Marble of fine colour, and susceptible of a high polish, is raised from quarries near Ledwithstown. It is much used for chimney-pieces.

A great portion of the northern part of the county is of a rough, untractable quality, affording little encouragement for agricultural speculations; but all the more level districts, where these are not covered with bog, are of a good quality. The soil is mostly rich, and of easy culture.

The statements of the population at various periods, with the authorities on which they rest, are as follow:—

1760	De Burgho	25,142
1792	Beaufort	50,100
1813	Parliamentary return	95,917
1821	Ditto	107,570
1831	Ditto	112,391

The census taken in 1834, by the commissioners of public instruction, having been collected according to dioceses instead of counties, prevents any specification of it here. It is observable that the rate of increase diminishes considerably in the latter period of this statement; a circumstance to be accounted for partly from the greater accuracy of the mode of calculating the numbers, and partly from the increased pressure of population upon the means of subsistence. The proportion of Protestants to Catholics is as one to ten, but the number of Protestant dissenters is inconsiderable. According to the parliamentary returns, the number of children receiving education in public or private schools was as follows:—

	Boys.	Girls.	Sex not ascertained.	Total.
1821,	4798	2623	...	7421
1824–6,	5746	3385	154	9285

Of the numbers stated in the latter of these returns, 1512 were Protestants of the established church, 7621 were Roman Catholics, 136 Dissenters, besides sixteen whose religious persuasion was not known. Of the total number of schools, amounting to 180, twelve, containing 870 pupils, were maintained by grants of public money; fifteen, containing 1003 pupils, were supported by voluntary contributions of societies or individuals; the remaining 153 depended wholly upon the fees of the pupils.

The county returned ten members to the Irish parliament, viz. two for the county at large, and two for each of the boroughs of Longford, Granard, Lanesborough, and Johnstown. It now returns only two county members. The state of the constituency was as follows at three periods, viz. 1. previously to the passing of the Catholic relief bill; 2. subsequently to that measure, but previous to the reform act; 3. after the reform act, viz.

	L.50.	L.20.	L.10.	40s.	Total.
Jan. 1, 1829,	155	45	...	1362	1562
— 1830,	168	67	132	...	367
— 1832,	192	151	951	...	1294

The mode of tillage is such as is common throughout most parts of Ireland, namely, either ploughing up the lea, or manuring the surface highly and planting potatoes on it with the spade. The usual rotation of crops is, potatoes, bear, and oats. Wheat is also grown. In the vicinity of Ballymahon are some rich lands in a high state of cultivation, and tracts of excellent meadow. The low lands along the Inny produce a coarse kind of hay mixed with reeds; it is chiefly used for thatching. The black cattle and horses in the southern district are of a good kind. The breed of the former has been considerably improved by judicious crossing with the best English bulls.

The manufactures are confined to those which are necessary to supply the limited wants of an agricultural population. The principal are linen, frize, linsey-woolsey, for the garments of men and women, and leather for shoes and harness. The Royal Canal, which passes through the centre of the county, has greatly increased the inland trade.

The peasantry are a shrewd, intelligent, and industrious race, fond of manly exercises and active amusements, such as hurling, wrestling, foot-ball, and swimming. Their pastime on Sunday evenings is dancing for a cake set up on a pole. English and Irish are both spoken. The most prevalent disease is fever, particularly in the hilly districts. Its access is generally attributed to the neglect of cleanliness and the poverty of the people. The climate in general is healthy. Several persons are known to have lived to the advanced age of a hundred years.

The customs of the inhabitants deviate in few particulars from those observable in other parts of Ireland. The first day of the year, month, and week are considered as the most lucky days for commencing an undertaking. Friday is one of the cross-days, therefore every one avoids removing to a new habitation on that day. A Saturday's flitting is also said to make a short sitting. For a fortnight previous to Shrove-Tuesday, the great day for weddings, the boys amuse themselves by running in disguise through the villages, proclaiming the names of the parties about to be married, or whom they wish to have thought so. The first of May, Hallow-Eve, and Christmas, are celebrated with all the usual honours. Bull-baiting is one of the sports indulged in on St Stephen's day.

The only vestige of remote antiquity worthy of special notice is a tumulus at one end of the town of Granard, said to have been a Danish rath, and called the Moate of Granard. It commands a view of six or seven surrounding counties. Though several ruins of monastic buildings may still be traced, few memorials of their history have been preserved. The erection of those at Ardagh, Lerha or Granard, Clonebrone, and Drumcheo, is attributed to St Patrick. Those of Longford, Abbeyshruel, and Ballynasaggard, were founded by members of the O'Ferral family. Abbey Deirg was built by O'Quin. A house of gray friars, dedicated to St John, gave name to Johnstown. At Lanesborough are some ruins said to have been part of a monastery, but no historical trace of such a foundation there can be discovered. The island of Inchimore in Lough Gawnagh, and those of Innisbofin, Innisclothran, and Innismacsaint, in Lough Reagh, were each at some remote period the site of a religious house now in utter ruin.

The castle of Longford, once the mansion of the O'Ferrals, was taken at the commencement of the war of 1641, and the garrison slaughtered after their surrender upon terms. Castle Forbes, in the same neighbourhood, made a gallant resistance during the same period, under the command of the widow of Sir Arthur Forbes, until reduced by famine. Rathcline, placed in a highly romantic position near Lanesborough, was dismantled by Cromwell, and burned in the subsequent wars between William and James. The castles of Ballymahon, Barnacor, and Castlecor, were built to command passes over the Inny. Of these, the last named has suffered, not only by the ravages of time, but by excavations made in order to discover concealed money, imagined to have been buried in its interior.

The seats of the gentry are numerous. Carrickglass on the Camlin, belonging to the Newcomen family, is a fine residence; as is also Castle Forbes, the seat of the Earl of Granard. Edgeworthstown will long be noted in the annals of British literature as the residence of the Edgeworth family. Castlecor, the seat of the Hussey family, and said to have been modelled after the round tower of Windsor Castle, is more remarkable for eccentricity of appearance than architectural elegance or domestic convenience. Tirlicken was built by Lord Annaly, near the ruins of a former edifice of the same name, the seat of Sir Connel O'Ferral, which was forfeited in 1641. This county is also celebrated for having given birth to Oliver Goldsmith, a writer, the pride of his country, and the delight of elegant literature. He was born at Pallas, a village near Ballymahon, where it is said that the originals of much that he has enshrined in immortal verse in his poem of the *Deserted Village* may still be traced.

Longford, the county town, is situated on the river Camlin, in the midst of an extensive plain, interrupted only by the hill of Fenaghfadd, which rises to a height of 200 feet, at some distance south of the place. It contains a Protestant church and a Roman Catholic chapel, a gaol built according to the newly-suggested plans of classification, a court-house, an infirmary, and a market-house. It has a tolerable share of inland trade, which has latterly been much enlarged by the extension of the line of the Royal Canal through it, and also a market for yarn and unbleached linen. Here is also a brewery and several flour mills. Its population amounted in 1831 to 4354 souls. The other towns the population of which exceeds a thousand souls are as follow: Granard, 2058; Ballymahon, 1081; and Edgeworthstown, 1001.

LONGIMETRY, the art of measuring length, both accessible and inaccessible.

LONGING, a preternatural appetite for meat and drink. It is called *pica*, from the bird of that name, which is said to be subject to the same disorder. The disorder consists both in a desire of unusual things to eat and drink, and in being soon tired of one and wanting another. It is called *malacia*, from *μαλακος*, *weak*.

LONGINICO, a town of Turkey in Europe, in the Morea, anciently called *Olympia*, and famous as having been the place where the Olympic games were celebrated. The temple of Jupiter Olympus was about a mile distant from this place. It is situated on the river Alpheus, ten miles from its mouth, and fifty south of Lepanto. Long. 22. 0. E. Lat. 37. 30. N.

LONGINUS, DIONYSIUS CASSIUS, a celebrated Greek critic and grammarian, was, according to Fabricius, grandson of Cassius Longinus, who is mentioned by Plutarch (*Symp.* ix. 1); but this is a mere conjecture, unsupported by any adequate proof. The precise period of his birth is unknown, though it is not unlikely that it took place about A. D. 213, in the reign of Caracalla, as he may be supposed to have preceded by at least twenty years his pupil Porphyry, who was born A. D. 233. There is no doubt that his death took place A. D. 273, when the Emperor Aurelian took Palmyra. The place of his birth is also a matter of much uncertainty, as it is nowhere distinctly stated. The circumstance of his understanding the Syrian language, and his uncle being from Emesa in Syria, has caused some to fix on that city as his native place; and others have suspected, though with still less appearance of probability, that he was from Palmyra. His uncle Fronto enjoyed considerable reputation as a teacher of philosophy at Athens; and, amongst other pupils, he had Philostratus, who is known to us by his life of the philosopher and prophet Apollonius of Tyana, which is still preserved. It would appear that Fronto was much attached to his nephew, whom he made his heir; and from him Longinus most probably derived the rudiments of his education. In his earlier years we find, from a fragment of one of his works preserved by Porphyry in his life of Plotinus, that he travelled much, and enjoyed the opportunity of becoming acquainted with all the most distinguished philosophers of his time. He gives the names of upwards of twenty, but, with the exception of Ammonius Saccas, Origen, Plotinus, and Amelius, their celebrity was not sufficient to rescue them from oblivion. Ammonius taught the Platonic philosophy at Alexandria in Egypt, and at this time appears to have enjoyed a high reputation. The doctrines which he advocated, and his particular system, are known to us from the works of his pupil Plotinus, and the epitome of Hierocles in Photius. (*Cod.* ccxiv. p. 550.) The philosopher Origen, the master of Longinus, is not to be confounded with the Christian bishop of the same name, who was born at Alexandria, A. D. 185.

After Longinus had made himself completely master of the philosophy of Plato, which he preferred to that of every other sect, he took up his residence at Athens, and devoted himself to the instruction of youth in grammar and philosophy. Here Porphyry attended him, and derived much of that information which he afterwards employed against the Christian religion. After a long residence at Athens, he proceeded to the East, and joined Zenobia, queen of Palmyra, who had a little before succeeded to the government of the kingdom upon the death of her husband Odenathus. He became her preceptor in the Greek language, and she even consulted him respecting the administration of her affairs. Zenobia was persuaded by her courtiers that she was sufficiently powerful to refuse obedience to the commands of Aurelian, who had some time before succeeded to the Roman empire. Aurelian was more particularly amazed by the haughty style of a letter which was sent by Zenobia in answer to his demands, and which was said to have been dictated by Longinus. This letter is found in the life of Aurelian by Flavius Vopiscus (*Aug. Script.* vol. ii. p. 174, ed. Bipont.). Palmyra was taken after an obstinate siege, and Aurelian was ungenerous enough to punish him by death for the insult which had been offered to his dignity by the letter he had dictated. Longinus died without indulging in vain regrets, and in a manner worthy of his character as a philosopher, consoling the companions of his misfortunes. (Zosim. i. 56.)

He was the author of many works of criticism, but, with the exception of a few fragments, and of his treatise Πεϱι Ὕψους, On the Sublime, they have all perished. This treatise is addressed to his friend Posthumus Terentianus, and is an able disquisition on the various sources from which sublimity in writing is derived, illustrated by examples selected from the works of the most distinguished authors of antiquity. The Old Testament was not unknown to him, as he has quoted as one of the noblest specimens of the sublime, the celebrated passage in Genesis: "And God said, Let there be light; and there was light." We find also in a fragment (*E. Cod. MS. to Vat.*) that he ranks Paul of Tarsus, as he styles the apostle, with Demosthenes and the more celebrated orators of Greece. He was no doubt acquainted with the doctrines of Christianity; and the noble sentiments which he at times expresses may not unreasonably be ascribed to this circumstance. In the epilogue to his treatise, he speaks most feelingly of the corruption which pervaded every part of the world, and of the little attention which was paid to the cultivation of the intellect. The moral degeneracy of the age he in a great measure ascribes to the absence of free institutions, and quotes the well-known lines of the Odyssey, which Pope has thus translated:—

> Jove fixed it certain, that whatever day
> Makes man a slave, takes half his worth away.

It is remarkable that such sentiments should be found at this period of the world; but there can be no doubt that they were the genuine expression of his feelings. This treatise has been frequently edited, and one of the best editions is that by Hudson, Oxford, 1710. It has also been edited by Weiske, Weigel, 1809; and by Toup, Oxford, 1778. It has been translated into English by Smith, 1739; and into German by J. G. Schlosser, Leipzig, 1781, and by Von Heineken, Basel, 1784.

LONGITUDE is the distance of any place from another eastward or westward, counted in degrees upon the equator; but when the distance is reckoned by leagues or miles, and not in degrees, or in degrees on the meridian, and not of the parallel of latitude, in which case it includes both latitude and longitude, it is called *departure*.

To find the longitude at sea is a problem to which the attention of navigators and mathematicians has been directed ever since navigation began to be improved. The importance of this problem soon became so well known, that, in 1598, Philip III. of Spain offered a reward of a thousand crowns for the solution; and his example was soon followed by the states-general, who offered a premium of ten thousand florins. In 1714 an act was passed in the British parliament, empowering certain commissioners to introduce a bill for a sum not exceeding L.2000, for defraying the necessary expenses of experiments for ascertaining this point, and likewise for granting a reward to the person who should make any progress in the solution, proportional to the degree of accuracy with which the solution was performed. Ten thousand pounds were to be granted if the longitude should be determined to one degree of a great circle, or sixty geographical miles; fifteen thousand, if to two thirds of that distance; and twenty thousand, if to half the distance. In consequence of these proffered rewards, innumerable attempts were made to discover this important secret. The first was that of John Morin, professor of mathematics at Paris, who proposed it to Cardinal Richelieu; and though it was judged insufficient, on account of the imperfection of the lunar tables, a pension of two thousand livres per annum was procured for him in 1645 by Cardinal Mazarin. Gemma Frisius had indeed in 1530 projected a method of finding the longitude by means of watches, which at that time were newly invented; but the structure of these machines was then by far too imperfect to admit of their being employed for this purpose; nor even in 1631, when Metius made a similar attempt, had they undergone any considerable improvement. But, about the year 1664, Dr Hooke and Mr Huygens effected a very great improvement in watchmaking, by the application of the pendulum spring. Dr Hooke having quarrelled with the ministry, no experiment was made with any of his machines; but many were made with those of Mr Huygens. One experiment particularly, made by Major Holmes in a voyage from the coast of Guinea in 1665, answered so well, that Mr Huygens was encouraged to improve the structure of his watches; but it was found that the variations of heat and cold produced such alterations in the rate of going, that unless this could be remedied, the watches would be of little use in determining the longitude.

In 1714 Henry Sully, an Englishman, printed a small tract at Vienna upon the subject of watchmaking. Having afterwards removed to Paris, he applied himself to the improvement of time-keepers, with a view to the discovery of the longitude. He taught the famous Julian de Roy; and this gentleman, along with his son and M. Berthoud, soon turned their attention to the subject. But though experiments were made at sea with some of their watches, it does not appear that they had been able to accomplish any thing of importance with reference to the main point. The first who succeeded in any considerable degree was Mr John Harrison, who, in 1726, produced a watch which went so exactly, that for ten years together it did not err above one second in a month. In 1736 it was tried in a voyage to Lisbon and back again, on board one of his majesty's ships, during which it corrected an error of a degree and a half in the computation of the ship's reckoning. In consequence of this he received public encouragement to proceed, and by the year 1761 he had finished three time-keepers, each of them more accurate than the former. The last turned out so much to his satisfaction, that he now applied to the commissioners of longitude for leave to make an experiment with his watch in a voyage to the

West Indies. Permission being granted, his son Mr William Harrison set out in his majesty's ship the Deptford, for Jamaica, in the month of November 1761. This trial was attended with all imaginable success. The longitude of the island, as determined by the time-keeper, differed from that found by astronomical observations only by one minute and a quarter of the equator; the longitudes of places seen by the way being also determined with great exactness. On the ship's return to England, it was found to have erred no more during the whole voyage than 1′ 54½″ in time, which is little more than twenty-eight miles in distance; and this being within the limits prescribed by the act, the inventor claimed the whole L.20,000 offered by government. Objections to this claim, however, were soon started. Doubts were pretended about the real longitude of Jamaica, as well as the manner in which the time had been found both there and at Portsmouth. It was alleged also, that although the time-keeper happened to be right at Jamaica, and after its return to England, this was by no means a proof that it had always been so in the intermediate time. In consequence of these allegations, another trial was appointed to be made in a voyage to Barbadoes. Precautions were now taken to obviate as many of these objections as possible. The commissioners sent out proper persons to make astronomical observations at that island, which, when compared with others in England, would ascertain beyond a doubt its true situation. In 1764 the younger Mr Harrison set sail for Barbadoes; and the result of the experiment was, that the difference of longitude between Portsmouth and Barbadoes was shown by the time-keeper to be 3h. 55′ 3″, and by astronomical observations to be 3h. 54′ 20″, the error being now only 43″ of time, or 10′ 45″ of longitude. In consequence of this and the former trials, Mr Harrison received one half of the reward promised, upon making a discovery of the principles on which his time-keeper had been constructed. He was likewise promised the other half of the reward as soon as time-keepers should be constructed by other artists which should answer the purpose as well as those made by Mr Harrison himself. At this time he delivered up all his time-keepers, the last of which was sent to Greenwich to be tried by Dr Maskelyne, the astronomer-royal. On trial, however, it was found to go with much less regularity than had been expected; but Mr Harrison attributed this to his having made some experiments with it which he had not time to finish when he was ordered to deliver up the watch. Soon after this an agreement was made by the commissioners with Mr Kendall to construct a watch upon Mr Harrison's principles; and this was found upon trial to answer the purpose even better than any which Harrison himself had constructed. This watch was sent out with Captain Cook in 1772, and during all the time of his voyage round the world in 1772, 1773, 1774, and 1775, never erred quite 14½ seconds per day, in consequence of which the House of Commons in 1774 ordered the other L.10,000 to be paid to Mr Harrison. Since that period, however, still greater accuracy has been attained in the construction of chronometers.

Thus the method of constructing time-keepers for discovering the longitude seems to be brought to as great a degree of perfection as can well be expected. Still, however, as these watches are subject to accidents, and may thus alter the rate of their going without any possibility of a discovery, it is necessary that some other method should be employed in order to correct from time to time those errors which may arise either from the natural going of the watch, or from any accident which may happen to it. Methods of this kind are all founded upon celestial observations of some kind or other; and for such methods, or even for an improvement in time-keepers, rewards are still held out by government. After the discoveries made by Mr Harrison, the act concerning the longitude was repealed, excepting so much of it as related to the constructing, printing, and publishing of the Nautical Almanac, and other useful tables. It was also enacted, that any person who shall discover a method for finding the longitude by means of a time-keeper, the principles of which have not hitherto been made public, shall be entitled to a reward of L.5000, if, after certain trials made by the commissioners, the said method shall enable a ship to keep her longitude, during a voyage of six months, within sixty geographical miles, or a degree of a great circle. If the ship keeps her longitude within forty geographical miles for that time, the inventor is entitled to a reward of L.7500, and to L.10,000 if the longitude is kept within half a degree. If the method be by improved astronomical tables, the author becomes entitled to L.5000 when they show the distance of the moon from the sun and stars within fifteen seconds of a degree, answering to about seven minutes of longitude, after allowing half a degree for errors of observation and under certain restrictions, and after comparison with astronomical observations for a period of eighteen and a half years, during which the lunar irregularities are supposed to be completed. The same rewards are likewise offered to the person who shall with similar accuracy discover any other method of finding the longitude.

These methods require celestial observations; and any of the phenomena, such as the different apparent places of stars with regard to the moon, the beginning and ending of eclipses, &c. will answer the purpose. But it is absolutely necessary that some variation should be perceptible in the phenomenon in the space of two minutes; for even this short space of time will produce an error of forty miles in longitude. The most proper phenomena therefore for determining the longitude in this manner are the eclipses of Jupiter's satellites. Tables of their motions have therefore been constructed, and carefully corrected from time to time, as the mutual attractions of these bodies are found greatly to disturb the regularity of their motions. The difficulty here, however, is to observe these eclipses at sea; and this difficulty has been found so great, that no person seems able to surmount it. The difficulty arises from the violent agitation of the ship in the ocean, for which no adequate remedy has ever yet been found. Mr Christopher Irwin indeed invented a machine which he called a *marine chair*, with a view to prevent the effects of this agitation; but on trying it on a voyage to Barbadoes, it was found to be totally useless.

A whimsical method of finding the longitude was proposed by Whiston and Ditton, from the report and flash of great guns. The motion of sound is known to be nearly equable, from whatever body it proceeds, or whatever be the medium through which it is transmitted. Supposing therefore a mortar to be fired at any place the longitude of which is known, the difference between the moment that the flash is seen and the report is heard will give the distance between the two places; hence, if we know the latitudes of these places, their longitudes must also be known. If the exact time of the explosion be known at the place where it happens, the difference of time at the place where it is heard will likewise give the difference of longitude. Let us next suppose the mortar to be loaded with an iron shell filled with combustible matter, and fired perpendicularly upwards into the air, the shell will be carried to the height of a mile, and will be seen at the distance of near 100; and hence, supposing that neither the flash of the mortar should be seen nor the report heard, still the longitude might be determined by the altitude of the shell above the horizon. According to this plan, mortars were to be fired at certain times and at proper stations along all frequented coasts, for the direction of mariners. This indeed might be of use, and in stormy weather might be a kind of improvement in lighthouses, or a proper addition to them; but with regard to the determination of longitudes, it is evidently ridiculous.

We shall now proceed to give some practical directions for finding the longitude at sea by proper celestial observations, exclusive of those of Jupiter's satellites, which, for the reasons just mentioned, cannot be practised at sea. In the first place, however, it will be necessary to point out some of those difficulties which stand in the way, and which render even this method of finding the longitude precarious and uncertain. These consist principally in the reduction of the observations of the heavenly bodies made on the surface of the earth to similar observations supposed to be made at the centre, which is the only place where the celestial bodies appear in their proper situation. It is also very difficult to make proper allowances for the refraction of the atmosphere, by which all objects appear higher than they really are; and another difficulty arises from the parallaxes of the heavenly bodies, which make them, particularly the moon, appear lower than they would otherwise do, excepting when they are in the very zenith. It is also well known, that the nearer the horizon any celestial body is, the greater its parallax will be; and as the parallax and refraction act in opposite ways, the former depressing and the latter raising the object, it is plain that great difficulties must arise from this circumstance. The sun, for instance, whose parallax is less than the refraction, must always appear higher than he really is; but, on the other hand, the moon, whose parallax is greater than her refraction, must always appear lower.

To facilitate the necessary observations of the celestial bodies, the commissioners of longitude have caused an Ephemeris or Nautical Almanac to be published annually, containing every requisite for solving this important problem which can be put into any form of tables. But whatever may be done in this way, it will still be necessary to make the requisite preparations concerning the dip of the horizon, the refraction, semidiameters, parallax, &c. in order to reduce the apparent to the true altitudes and distances; and for this we shall subjoin two general rules.

The principal observation for finding the longitude at sea is that of the moon from the sun, or from some remarkable star near the zodiac. To do this, the operator must be furnished with a watch which can be depended upon for keeping time within a minute for six hours; and with a good Hadley's quadrant, or, which is preferable, a sextant; and this last instrument will still be fitter for the purpose if it be furnished with a screw for moving the index gradually, and likewise an additional dark glass, but not so dark as the common kind, for taking off the glare of the moon's light in observing her distance from a star. A small telescope, which magnifies three or four times, is also necessary, to render the contact of a star with the moon's limb more discernible. A magnifying glass of one and a half or two inches focus will likewise greatly assist the operator in reading off his observations with facility and despatch.

1. *To make the observation.*—Having examined and adjusted his instrument as well as possible, the observer is next to proceed in the following manner: If the distance of the moon from the sun is to be observed, turn down one of the screens; look at the moon directly through the transparent part of the horizon-glass, and, keeping her in view, gently move the index till the sun's image be brought into the silvered part of that glass. Bring the nearest limbs of both objects into contact, and let the quadrant librate a little upon the lunar ray, by which means the sun will appear to rise and fall by the side of the moon; in which motion the nearest limbs must be made to touch one another exactly by moving the index. The observation is then made; and the division coinciding with that on the vernier scale will show the distance of the nearest limbs of the objects.

If the distance of the moon from a star is to be observed when the moon is very bright, turn down the lightest screen, or use a dark glass lighter than the screens, and designed for this particular purpose; look at the star directly through the transparent part of the horizon-glass, and, keeping it there, move the index till the moon's image be brought into the silvered part of the same glass. Make the quadrant librate gently on the star's ray, and the moon will appear to rise and fall by the star; move the index between the librations, until the moon's enlightened limb is exactly touched by the star, and then the observation is made. In these operations, the plane of the quadrant must always pass through the two objects, the distance of which is to be observed; and for this purpose it must be placed in various positions, according to the situation of the objects, which will soon be rendered easy by practice.

The observation being made, some person, at the very instant that the operator calls, must observe by the watch the exact hour, minute, and quarter minute, if there be no second hand, in order to find the apparent time; and at the same instant, or as quickly as possible, two assistants must take the altitudes of those objects the distance of which is observed; after which the observations necessary for finding the longitude are completed.

The Ephemeris shows the moon's distance from the sun, and likewise from proper stars, to every three hours of apparent time for the meridian of Greenwich; and, that the greater number of opportunities of observing this luminary may be given, her distance is generally set down from at least one object on each side of her. Her distance from the sun is set down whilst it is between 40 and 120 degrees; so that, by means of a sextant, it may be observed for two or three days after her first and before her last quarter. When the moon is between 40 and 90 degrees from the sun, her distance is set down both from the sun and from a star on the contrary side; and, lastly, when the distance is above 120 degrees, the distance is set down from two stars, one on each side of her. The distance of the moon from objects on the east side of her is found in the Ephemeris in the eighth and ninth pages of the month; and her distance from objects on the west is found in the tenth and eleventh pages of the month.

When the Ephemeris is used, the distance of the moon must only be observed from those stars the distance of which is set down there; and these afford a ready means of knowing the star from which her distance ought to be observed. The observer has then nothing more to do than to set his index to the distance roughly computed at the apparent time, estimated nearly for the meridian at Greenwich; after which he is to look to the east or west of the moon, according as the distance of the star is found in the eighth or ninth, or in the tenth or eleventh pages of the month; and having found the moon upon the horizon-glass, the star will easily be found by sweeping with the quadrant to the right or left, provided the air be clear and the star be in the line of the moon's shortest axis produced. The time at Greenwich is estimated by turning into time the supposed longitude from that place, and adding it to the apparent time at the ship, or subtracting it, as occasion requires. The distance of the moon from the sun or a star is roughly found at this time, by saying, As 180 minutes (the number contained in three hours) is to the difference in minutes between this nearly estimated time and the next preceding time set down in the Ephemeris, so is the difference in minutes between the distance in the Ephemeris for the next preceding and next following times to a number of minutes, which being added to the next preceding distance, or subtracted from it, according as it is increasing or decreasing, will give the distance nearly at the time when the observation is to be made, and to which the index must be set.

An easier method of finding the angular distance is by bringing the objects nearly into contact in the common way, and then fixing the index tight to a certain degree and minute, waiting until the objects are nearly in contact, giving notice to the assistants to get ready with the altitudes, and when the objects are exactly in contact, to call for the altitudes and the exact time by the watch. The observer may then prepare for taking another distance, by setting his index three or four minutes backwards or forwards, as the objects happen to be receding from or approaching to each other, and then proceeding to take the distance, altitudes, and time by the watch, as before. Thus the observer may take as many distances as he thinks proper; but four at the distance of three minutes, or three at the distance of four minutes, will at all times be sufficient. Thus not only the eye of the observer will be less fatigued, but he will likewise be enabled to manage his instrument with much greater facility in every direction, a vertical one only excepted. If, in taking the distances, the middle one can be taken at any even division on the arch, such as a degree, or a degree and twenty or forty minutes, that distance will be independent of the nonius division, and consequently free from those errors which frequently arise from the inequality of that division in several parts of the graduated arch. The observation ought always to be made about two hours before or after noon; and the true time may be found by the altitude of the sun taken at the precise time of the distance. If three distances are taken, then find the time by the altitude corresponding with the middle distance; and thus the observation will be secured from any error arising from the irregularity of the going of the watch. As the time, however, found by the altitude of a star cannot be depended upon, because of the uncertainty of the horizon in the night, the best way of determining the time for a night observation will be by two altitudes of the sun; one taken on the preceding afternoon, before he is within six degrees of the horizon, and the other on the next morning, when he is more than six degrees high. It must be observed, however, that in order to follow these directions, it is necessary that the atmosphere should be pretty free from clouds, otherwise the observer must take the observations at such times as he can best obtain them.

2. *To reduce the observed distance of the sun or a star from the moon to the true distance.*—1. Turn the longitude into time, and add it to the time at the ship if the longitude be west, but subtract it if it be east, which will give the supposed time at Greenwich. This we may call *reduced time.* 2. Find the nearest noon or midnight both before and after the reduced time in the seventh page of the month in the Ephemeris. 3. Take out the moon's semidiameter and horizontal parallaxes corresponding to these noons and midnights, and find their differences. Then say, as twelve hours is to the moon's semidiameter in twelve hours, so is the reduced time to a number of seconds, which, either added to or subtracted from the moon's semidiameter at the noon or midnight just mentioned, according as it is increasing or decreasing, will give her apparent semidiameter; to which add the correction of the Ephemeris, and the sum will be her true semidiameter at the reduced time. And as twelve hours is to the difference of the moon's horizontal parallax in twelve hours, so is the reduced time to a fourth number, which being added to or subtracted from the moon's horizontal parallax at the noon or midnight before the reduced time, according as it is increasing or decreasing, the sum or difference will be the moon's horizontal parallax at the reduced time. 4. If the reduced time be nearly any even part of twelve hours, viz. one sixth, one fourth, &c. these parts of the difference may be taken, and either added or subtracted according to the directions already given, without being at the trouble of working by the rule of proportion. 5. To the observed altitude of the sun's lower limb add the difference between the semidiameter and dip, and that sum will be his apparent altitude. 6. From the sun's refraction take his parallax in altitude, and the remainder will be the correction of the sun's altitude. 7. From the star's observed altitude take the dip of the horizon, and the remainder will be the apparent altitude. 8. The refraction of a star will be the correction of its altitude. 9. Take the difference between the moon's semidiameter and dip, and add it to the observed altitude if her lower limb was taken, or subtract it if her upper limb was taken, and the sum or difference will be the apparent altitude of her centre. 10. From the proportional logarithm of the moon's horizontal parallax, obtained from the Nautical Almanac (increasing its index by 10), taking the logarithmic cosine of the moon's apparent altitude, the remainder will be the proportional logarithm of her parallax in altitude; from which take her refraction, and the remainder will be the correction of the moon's altitude. 11. To the observed distance of the moon from a star add her semidiameter if the nearest limb be taken, but subtract it if the farthest limb be taken, and the sum or difference will be the apparent distance. 12. To the observed distance of the sun and moon add both their semidiameters, and the sum will be the apparent distance of their centres.

3. *To find the true distance of the objects, having their apparent altitudes and distances.*—1. To the proportional logarithm of the correction of the sun or star's altitude, add the logarithmic cosine of the sun or star's apparent altitude, the logarithmic sine of the apparent distance of the moon from the sun or star, and the logarithmic cosecant of the moon's apparent altitude. The sum of these, rejecting thirty from the index, will be the proportional logarithm of the first angle. 2. To the proportional logarithm of the correction of the sun or star's altitude, add the logarithmic cotangent of the sun or star's apparent altitude, and the logarithmic tangent of the apparent distance of the moon from the sun or star. The sum of these, rejecting twenty in the index, will be the proportional logarithm of the second angle. 3. Take the difference between the first and second angles, adding it to the apparent distance if it be less than ninety, and the first angle be greater than the second; but subtracting it if the second be greater than the first. If the distance be greater than ninety, the sum of the angles must be added to the apparent distance, which will give the distance corrected for the refraction of the sun or star. 4. To the proportional logarithm of the correction of the moon's altitude, add the logarithmic cosine of her apparent altitude, the logarithmic sine of the distance corrected for the sun or star's refraction, and the logarithmic cosecant of the sun's or star's apparent altitude. The sum, rejecting thirty in the index, will be the proportional logarithm of the third angle. 5. To the proportional logarithm of the correction of the moon's apparent altitude, add the logarithmic cotangent of her apparent altitude, and the tangent of the distance corrected for the sun or star's refraction; their sum, rejecting twenty in the index, will be the proportional logarithm of the fourth angle. 6. Take the difference between the third and fourth angles, and subtract it from the distance corrected for the sun or star's refraction if less than ninety and the third angle be greater than the fourth, or add it to the distance if the fourth angle be greater than the third; but if the distance be more than ninety, the sum of the angles must be sub-

tracted from it, to give the distance corrected for the sun or star's refraction, and the principal effects of the moon's parallax. 7. In the Ephemeris, look for the distance corrected for the sun and star's refraction, and the moon's parallax in the top column, and the correction of her altitude in the left-hand-side column; take out the number of seconds that stand under the former, and opposite to the latter. Look again in the same table for the corrected distance in the top column, and the principal effects of the moon's parallax in the left-hand-side column, and take out the number of seconds. The difference between these two numbers must be added to the corrected distance if less than ninety, but subtracted from it if it be greater; and the sum or difference will be the true distance.

4. *To determine the longitude after having obtained the true distance.*—Look in the Ephemeris amongst the distances of the objects for the computed distance between the moon and the other object observed on the given day. If it be found there, the time at Greenwich will be at the top of the column; but if it falls between two distances in the Ephemeris which stand immediately before and after it, and also the difference between the distance standing before and the computed distance, then take the proportional logarithms of the first and second differences, and the difference between these two logarithms will be the proportional logarithm of a number of hours, minutes, and seconds; which being added to the time standing over the first distance, will give the true time at Greenwich. Or it may be found by saying, As the first difference is to three hours, so is the second difference to a proportional part of time, which being added as above directed, will give the time at Greenwich. The difference between Greenwich time and that at the ship, turned into longitude, will be that at the time the observations were made; and will be east if the time at the ship is greatest, but west if it is least.

Having given these general directions, we shall next proceed to show some particular examples of finding the longitude at sea by all the different methods in which it is usually tried.

1. *To find the longitude by computation from the ship's course.*—Were it possible to keep an accurate account of the distance the ship has run, and to measure it exactly by the log or by any other means, then both latitude and longitude would easily be found by settling the ship's account to that time. For the course and distance being known, the difference of latitude and departure is readily found by the Traverse Table; and the difference of longitude being known, the true longitude and latitude would also be known. A variety of causes, however, concur to render this computation inaccurate, particularly the ship's continual deflection from the course set, by her playing to the right and left round her centre of gravity; the unequal care of those at the helm; and the distance supposed to be sailed being erroneous, on account of stormy seas, unsteady winds, currents, &c. for which it seems impossible to make any due allowance. The place of the ship, however, is judged of by finding the latitude every day, if possible, by observations; and if the latitude found by observation agrees with that by the reckoning, it is presumed that the ship's place is properly determined; but if they disagree, it is concluded that the account of the longitude stands in need of correction, as the latitude by observation is always to be depended upon.

Currents very often occasion errors in the computation of a ship's place. The causes of these in the great depths of the ocean are not well known, though many of the motions near the shore can be accounted for. It is supposed that some of those in the great oceans are owing to the tide following the moon, and a certain libration of the waters arising therefrom; and likewise that the unsettled nature of these currents may be owing to the changes in the moon's declination. In the torrid zone, however, a considerable current is occasioned by the trade winds, the motion being constantly to the west, at the rate of about eight or ten miles per day. At the extremities of the trade winds, or near the thirtieth degree of north or south latitude, the currents are probably compounded of this motion to the westward, and of one towards the equator; and hence all ships sailing within these limits ought to allow a course each day for the current.

When the error is supposed to have been occasioned by a current, it ought if possible to be tried whether the case is so or not; or we must make a reasonable estimate of its drift and course. Then with the setting and drift, as a course and distance, find the difference of latitude and departure; with which the dead reckoning is to be increased or diminished; and if the latitude thus corrected agrees with that by observation, the departure thus corrected may be safely taken as true, and thus the ship's place with regard to the longitude determined.

Example. Suppose a ship in twenty-four hours finds, by her dead reckoning, that she has made ninety-six miles of difference of latitude north, and thirty-eight miles of departure west; but by observation finds her difference of latitude 112, and on trial that there is a current which in twenty-four hours makes a difference of sixteen miles latitude north, and ten miles of departure east: Required the ship's departure.

	Miles.		Miles.
Diff. lat. by account	96 N.	Departure by account	38 W.
Diff. lat. by current	16 N.	Departure by current	10
True diff. lat.........	112		28 W.

Here the dead reckoning corrected by the current gives the difference of latitude 112 miles, which is the same as that found by observation; and hence the departure twenty-eight is taken as the true one.

When the error is supposed to arise from the courses and distances, we must observe, that if the difference of latitude is much more than the departure, or the direct course has been within three points of the meridian, the error is most probably in the distance. But if the departure be much greater than the difference of latitude, or the direct course be within three points of the parallel, or more than five points from the meridian, the error is probably to be ascribed to the course. But if the courses in general are near the middle of the quadrant, the error may be either in the course, or in the distance, or both. This method admits of three cases.

1. When, by the dead reckoning, the difference of latitude is more than once and a half the departure, or when the course is less than three points: Find the course to the difference of latitude and departure, and with this course and the meridional difference of latitude by observation, find the difference of longitude.

2. When the dead reckoning is more than once and a half the difference of latitude, or when the course is more than five points: Find the course and distance, with the difference of latitude by observation, and departure by account; then, with the co-middle latitude by observation, and departure by account, find the difference of longitude.

3. When the difference of latitude and departure by account is nearly equal, or the direct course is between three and five points of the meridian: Find the course with the difference of latitude and departure by account since the last observation. With this course and the difference of latitude by observation find another departure. Take half the sum of these departures for the true one.

With the true departure and difference of latitude by observation find the true course; then with the true course and meridional difference of latitude find the difference of longitude.

2. *To find the longitude at sea by a variation-chart.*— Dr Halley having collected a great number of observations on the variation of the needle in many parts of the world, was enabled by that means to draw certain lines on Mercator's chart, showing the variation in all the places over which they passed in the year 1700, at which time he first published the chart; and hence the longitude of those places might be found by the chart, provided its latitude and variation were given. The rule is, draw a parallel of latitude on the chart, through the latitude found by observation; and the point where it cuts the curved line marked with the variation which had been observed will be the ship's place.

Example. A ship finds by observation the latitude to be 18° 20′ north, and the variation of the compass to be 4° west. Required the ship's place. Lay a ruler over 18° 20′ north, parallel to the equator; and the point where its edge cuts the curve of 4° west variation gives the ship's place, which will be found in about 27° 10′ west from London.

This method of finding the longitude, however, is attended with two inconveniences. 1. When the variation lines run east or west, or nearly so, it cannot be applied; though, as this happens only in certain parts of the world, a variation chart may be of great use for the rest. Even in those places indeed where the variation curves do run east or west, they may be of considerable use in correcting the latitude when meridian observations cannot be had, which frequently happens on the northern coasts of America, the Western Ocean, and about Newfoundland; for if the variation can be found exactly, the east and west curve answering to it will show the latitude. But, 2. The variation itself is subject to continual change, and a chart, though ever so perfect at first, must in time become totally useless; and hence the charts constructed by Dr Halley, though of great utility at the time of their publication, became at length almost entirely useless. A new one was published in 1746 by Messrs Mountaine and Dodson, which was so well received that in 1756 they again drew variation lines for that year, and published a third chart in the following year. They also presented to the Royal Society a curious paper concerning the variation of the magnetic needle, with a set of tables annexed containing the result of more than 50,000 observations, in six periodical reviews from the year 1700 to 1756 inclusive, adapted to every five degrees of latitude and longitude in the more frequented oceans; all of which were published in the Philosophical Transactions for 1757.

3. *To find the longitude by the sun's declination.*— Having made such observations on the sun as may enable us to find his declination at the place, take the difference between this computed declination and that shown at London by the Ephemeris; from which take also the daily difference of declination at that time; then say, as the daily difference of declination is to the above found difference, so is 360 degrees to the difference of longitude. In this method, however, a small error in the declination will make a great one in the longitude.

4. *To find the longitude by the moon's culminating.*— Seek in the Ephemeris for the time of her coming to the meridian on the given day and on the day following, and take their difference; also take the difference between the times of culminating on the same day as found in the Ephemeris and as observed; then say, as the daily difference in the Ephemeris is to the difference between the Ephemeris and observation, so is 360 degrees to the difference of longitude. In this method also a small difference in the culmination will occasion a great one in the longitude.

5. *By eclipses of the moon.*—This is done much in the same manner as by the eclipses of Jupiter's satellites; for if, in two or more distant places where an eclipse of the moon is visible, we carefully observe the times of the beginning and ending, the number of digits eclipsed, or the time when the shadow touches some remarkable spot, or when it leaves any particular spot on the moon, the difference of the times when the observations were made will give the difference of longitude. Phenomena of this kind, however, occur too seldom to be of much use.

6. In the 76th volume of the Philosophical Transactions, Mr Edward Pigot gives a very particular account of his method of determining the longitude and latitude of York; in which he also recommends the method of determining the longitude of places by observations of the *moon's transit over the meridian.* The instruments used in his observations were a gridiron pendulum clock, a two feet and a half reflector, an eighteen-inch quadrant made by Mr Bird, and a transit instrument made by Mr Sisson.

By these instruments an observation was made, on the 10th of September 1783, of the occultation of a star of the ninth magnitude by the moon, during an eclipse of that planet at York and Paris. Besides this, there were observations made of the immersions of φ *Aquarii* and δ *Piscium;* the result of all which was, that between Greenwich and York the difference of meridians was 4′ 27″.

In 1783, Mr Pigot informs us, that he thought of finding the difference of meridians by observing the meridian right ascensions of the moon's limb. This he thought had been quite original. But he found it afterwards in the Nautical Almanac for 1769, and in 1784 read a pamphlet on the same subject by the Abbé Toaldo; still he found that the great exactness of this method was not suspected, though he is convinced that it must soon be universally adopted in preference to that from the first satellite of Jupiter.

After giving a number of observations on the satellites of Jupiter, he concludes, that the exactness expected from observations, even on the first satellite, is much overrated. "Among the various objections," says he, "there is one I have often experienced, and which proceeds solely from the disposition of the eye, that of seeing more distinctly at one time than another. It may not be improper also to mention, that the observation I should have relied on as the best, that of 30th August 1785, marked *excellent,* is one of those most distant from the truth."

After giving a number of observations on the eclipse of the moon on the 10th of September 1783, our author concludes, that the eclipses of the moon's spots are in general too much neglected, and that it might be relied upon much more were the following circumstances attended to: 1. To be particular in specifying the clearness of the sky; 2. to choose such spots as are well defined, and leave no hesitation as to the part eclipsed; 3. every observer to employ, as far as possible, telescopes equally powerful, or at least to let the magnifying powers be the same. "A principal objection," says he, "may still be urged, viz. the difficulty of distinguishing the true shadow from the penumbra. Were this obviated, I believe the results would be more exact than from Jupiter's first satellite: undoubtedly the shadow appears better defined if magnified a little; but I am much inclined to think that, with high magnifying powers, there is greater certainty of choosing the same part of the shadow, which perhaps is more than a sufficient compensation for the loss of distinctness."

The following rule for meridian observations of the moon's limb is next laid down: "The increase of the moon's right ascension in twelve hours (or any given time found by computation), is to twelve hours as the increase of the moon's right ascension between two places found by observation is to the difference of meridians. We subjoin an example.

November 30, 1782.

h.	′	″		
13	12	57·62	Meridian transit of moon's second limb	By clock at Greenwich.
13	13	29·08	Ditto of α ♍	
		31·46	Difference of right ascension.	
13	14	8·05	Meridian transit of moon's second limb	By clock at York.
13	14	30·13	Ditto of α ♍	
		32·08	Difference at York	The clocks going nearly sidereal time, no correction is required.
		31·46	Difference at Greenwich	
		9·38	Increase of the moon's apparent right ascension between Greenwich and York, by observation.	

141″ in seconds of a degree, ditto, ditto, ditto.

The increase of the moon's right ascension for twelve hours, by computation, is 23,340 seconds; and twelve hours reduced into seconds is 43,200. Therefore, according to the rule stated above,

23,340″ : 43,200″ : diff. of merid. = 261″.

"These easy observations and short reduction," says Mr Pigot, "are the whole of the business. Instead of computing the moon's right ascension for twelve hours, I have constantly taken it from the Nautical Almanacs, which give it sufficiently exact, provided some attention be paid to the increase or decrease of the moon's motion. Were the following circumstances attended to, the results would be undoubtedly much more exact.

"1. Compare the observations with those which have been made in several other places. 2. Let several and the same stars be observed at these places. 3. Such stars as are nearest in right ascension and declination to the moon are infinitely preferable. 4. It cannot be too strongly urged, to get, as nearly as possible, an equal number of observations of each limb, to take a mean of each set, and then a mean of both means. This will in a great measure correct the error of telescopes and sight. 5. The adjustment of the telescopes to the eye of the observer before the observation is also very necessary, as the sight is subject to vary. 6. A principal error proceeds from the observation of the moon's limb, which may be considerably lessened, if certain little round spots near each limb were also observed in settled observatories; in which case the libration of the moon will perhaps be a consideration. 7. When the difference of meridians, or of the latitudes of places, is very considerable, the change of the moon's diameter becomes an equation.

"Though such are the requisites to use this method with advantage, only one or two of them have been employed in the observations that I have reduced. Two thirds of these observations had not even the same stars observed at Greenwich and York, and yet none of the results, except a doubtful one, differ 15″ from the mean; therefore I think we may expect a still greater exactness, perhaps within 10″, if the above particulars be attended to.

"When the same stars are not observed, it is necessary for the observers at both places to compute their right ascension from tables, in order to get the apparent right ascension of the moon's limb. Though this is not so satisfactory as by actual observation, still the difference will be trifling, provided the stars' right ascensions are accurately settled. I am also of opinion, that the same method can be put in practice by travellers with little trouble, and a transit instrument constructed so as to fix up with facility in any place. It is not necessary, perhaps, that the instrument should be perfectly in the meridian for a few seconds of time, provided stars, nearly in the same parallel of declination with the moon, are observed; nay, I am inclined to think, that if the instrument deviates even a quarter or half a degree, or more, sufficient exactness can be attained, as a table might be computed, showing the moon's parallax and motion for such deviation; which last may easily be found by the well-known method of observing stars whose difference of declination is considerable.

"As travellers very seldom meet with situations to observe stars near the pole, or find a proper object for determining the error of the line of collimation, I shall recommend the following method as original. Having computed the apparent right ascension of four, six, or more stars, which have nearly the same parallel of declination, observe half of them with the instrument inverted, and the other half when in its right position. If the difference of right ascensions between each set by observation agrees with the computation, there is no error; but if they disagree, half that disagreement is the error of the line of collimation. The same observations may also serve to determine whether the distances of the corresponding wires are equal. In case of necessity, each limb of the sun might be observed in the same manner, though probably with less precision. By a single trial I made above two years ago, the result was much more exact than I expected. Mayer's catalogue of stars will prove of great use to those that adopt the above method. I am rather surprised that the immersions of known stars of the sixth and seventh magnitude, behind the dark limb of the moon, are not constantly observed in fixed observatories, as they would frequently be of great use."

LONGITUDINAL, in general, denotes something placed lengthwise. Thus some of the fibres in the vessels of the human body are placed longitudinally, others transversely or across.

LONGOBARDI. See LOMBARDS.

LONGOMONTANUS, CHRISTIAN, a learned astronomer, born in a village of Denmark in 1562. He was the son of a ploughman, and during his studies had to suffer all the hardships to which his condition exposed him, dividing his time, like the philosopher Cleanthes, between the cultivation of the earth and the lessons he received from the minister of the place. At last, when he was fifteen, he stole away from his family, and went to the college at Wiburg, in which he spent eleven years; and though he was obliged to earn a livelihood, he applied himself to study with such ardour, that amongst other sciences he learned the mathematics in great perfection. He afterwards went to Copenhagen, where the professors of the university of that city soon conceived so high an opinion of him, that they recommended him to the celebrated Tycho Brahe. Longomontanus lived eight years with that celebrated astronomer, and was of great service to him in his observations and calculations. At length, being extremely desirous of obtaining a professor's chair in Denmark, Tycho Brahe consented, though with some reluctance, to deprive himself of his services; gave him a discharge filled with the highest testimonies of esteem; and furnished him with money for the expense of his journey. He obtained a professorship of mathematics in the university of Copenhagen in 1605, and discharged the duty of the office creditably until his death, which happened in 1647. He wrote many learned works, amused himself with endeavouring to square the circle, and pretended that he had actually discovered a mode of doing so; but Dr John Pell, an English mathematician, attacked him warmly on the subject, and proved that he was completely mistaken.

LONGTOWN, a town of Cumberland, on the Scotch borders, near the conflux of the Esk and Kirksop, nine miles from Carlisle, and 310 miles from London, It has a market on Thursday, and a charity school for the education of sixty children. The population amounted in 1831 to 2049.

LONGUS, a Greek sophist, author of a book entitled Ποιμενικα, or a romance containing the loves of Daphnis and Chloe. Huet, bishop of Avranches, speaks very favourably of this work; but he censures the obscene touches with which it is interspersed. None of the ancient authors mention Longus, so that the time when he lived cannot be fixed with certainty. There is an English translation of this author, which is ascribed to Mr Craggs, who was at one time secretary of state.

LONIGO, a city of Italy, the capital of a district in the Austrian delegation of Vicenza. It stands on the river Gua, and is well built and fortified. It is celebrated for a beautiful palace of the Rocca family, constructed by Palladio. It contains 5810 inhabitants, who carry on a brisk trade.

LONS LE SAUNIER, an arrondissement of the department of the Jura, in France, 712 square miles in extent. It is divided into eleven cantons, and subdivided into 298 communes, inhabited by 107,500 persons. The capital is the city of the same name. It is situated in a mountainous country, on the banks of the river Baille, and surrounded with picturesque but barren rocks, amongst which are some salt springs, and establishments for procuring refined salt. It contains 860 houses, and 6200 inhabitants. Long. 5. 30. E. Lat. 46. 36. N.

LONTAR PULO ISLE, an island in the Indian Ocean, separated from the peninsula of Malacca by a narrow strait. This and some of the neighbouring islands are inhabited by men whose whole pursuits are on the sea, that being the element from which they derive their whole subsistence. Agriculture is wholly unknown to them, and they are of simple and inoffensive manners.

LOOE, EAST, a borough and market-town of Cornwall, in the hundred of West, 233 miles from London. It is situated on the river of the same name, which runs into a creek on the shore. It has a market on Saturday. It returned two members to parliament, of which privilege, by the late law, it has been deprived. The population amounted in 1801 to 467, in 1811 to 608, in 1821 to 770, and in 1831 to 865.

LOOE, WEST, a borough and township in the parish of Talland, in Cornwall. It is opposite to East Looe, on the same river, with which it is connected by a bridge. It had formerly the privilege of returning two members to parliament, but of this it has been deprived by the reform act. It has a small but convenient harbour, defended by a battery. The population amounted in 1801 to 376, in 1811 to 433, in 1821 to 539, and in 1831 to 593.

LOO-CHOO ISLANDS, called LEWCHEW by Mr Macleod, and by others LIQUEO, or LIEOUKIOU. This group of islands is situated in the Eastern Ocean, to the south of Japan, about 400 or 500 miles east of the Chinese coast. They were little known to Europeans until they were visited by Captains Maxwell and Hall in the Alceste and Lyra in 1816, on their return from conveying Lord Amherst to China. Very full accounts have been published by Captain Hall and Mr Macleod of these islands, and of the climate and soil, as well as of the inhabitants, who appeared to these gentlemen to be extremely simple and interesting in their manners. These islands are in number thirty-six; but the only one of any great extent is the Great Loo-choo, which is thirty miles in length, and from twelve to fifteen in breadth. The climate is here a happy medium between the opposite extremes of heat and cold. Being situated in the middle of a vast ocean, these islands are refreshed by the sea breezes, which, blowing continually over them, produce an agreeable coolness. They are also well watered by small rivers and streamlets, which, rising in the central eminences, flow in different directions to the sea, and afford an abundant supply of excellent water. Being in the latitude of 26. N., the scenery, though not quite so rich, is, according to Captain Hall, even more pleasing to the eye than in countries nearer to the equator; the vegetation not being so luxuriant as to overload the landscape with foliage. The style of the landscape is on the whole decidedly tropical, though there is much variety; and the groves of pine trees give some parts of the country quite a European character. The orange and lime, the banyan of India, and the Norwegian fir, all thrive in Loo-choo. The mode of dressing the ground at Loo-choo is very neat, and resembles that of China, particularly in the process of manuring and irrigation. Tobacco, wheat, rice, Indian corn, millet, sweet potatoes, brinjals, and many other tropical vegetables, grow in great perfection at Loo-choo. Along the sides of the hills, and around the villages, the bamboo and rattan grow to a considerable size. But Captain Hall mentions that the pine was the most conspicuous tree which they observed on the island, rising to a great height and size. Some are forty feet in height, and three or four in girth. The cattle on this island are of a small black breed, and invariably used instead of horses for agricultural purposes. Hogs, goats, and poultry, with rice and a great variety of vegetables, form the chief food of the inhabitants, milk being seldom used. The English saw no geese on the island, nor sheep; but their horses, though very small and slender, were sufficiently strong for the natives. Their goats and pigs were also diminutive; but the poultry were large and excellent. These islands are not infested by any wild animals. They had no carts or wheeled carriages of any kind, all loads being carried by horses; and the roads, which are numerous, and generally kept in excellent order, measure generally from six to ten feet across.

The whole coast of Loo-choo, as well as of the other islands, is encircled with coral reefs, which do not appear above water; and when the weather is calm, and their situation is not pointed out by breakers, they are exceedingly dangerous to mariners. The Alceste, Captain Maxwell's ship, was several times in danger from these hidden rocks. This singular formation, which appears to be extending itself over the Pacific, was minutely examined by Captain Hall. After the sea has left it for some time, it becomes dry, and appears to be a compact rock; but no sooner does the tide rise again, and the waves begin to wash over it, than millions of coral worms, protruding themselves from holes in the surface, begin their operations; so that, from their prodigious numbers, the whole surface of the rock appears to be alive and in motion. These insects or worms cannot raise the rock above the surface of the water, and the level of the highest tide is accordingly the limit of the rock upwards, after which a horizontal field comes to be formed coincident with that plane, and perpendicular on all sides; and thus the reef, extending itself perpendicularly, and in all directions, becomes extremely dangerous to navigators. On the coast of Loo-choo there are several excellent harbours, particularly one, which is capacious and safe, and affords everywhere depth of water for the largest ships, with secure anchorage. Its banks consist of high rocks, overgrown with climbing plants and flowers.

These islands are inhabited by a singular and apparently amiable people. They are of a diminutive stature, not exceeding in their average height above five feet two inches. But they are strong, well-made, and athletic; and in complexion they are quite as fair as the natives of Spain and Portugal. They invariably manifested towards their English visitors the most gentle, polite, and humane dispositions, but with that jealousy of them as strangers which is peculiar to China, Japan, and all the neighbouring countries. They were at first extremely averse to the landing of their visitors, and it was only after long deliberations that they were induced to concede the liberty of doing so. But our people were confined to a small space on the sea-shore, under a burning sun; and it was only by renewed entreaties that they were allowed to extend their walks into the country. The natives, however, very freely visited the English ships, and examined them carefully in all their equipments and detail. They accepted readily the hospitality of the strangers, and conformed to their manners in every thing. In their interviews they always showed a natural good breeding, bowing whenever they spoke to the English, uncovering their heads in their presence, and, in drinking, bowing to all around. After they had permitted the English to land, many visits were paid; but they never admitted the strangers into the interior of their town, and even limited their walks within a certain space. Any attempt to pass these bounds was always resisted by the sentinels; not, however, by force, but by a polite request, and by representing, that if the orders of the court were transgressed, blame would fall upon them. Some overtures were made by Captain Maxwell for an interview with the king; but these were always steadily resisted, on the ground or pretence that no embassy or letters were brought from the king of England, to whom, however, the king of Loo-choo wrote a letter, which was unfortunately lost in the wreck of the Alceste. It was extremely difficult to bring about any intercourse with this people. Ordinary requests were made the subject of tedious negociations; and the most ungracious feature in their character was their uniform aversion to any intimate communication with their visitors. In one particular they manifested a rigid adherence to Chinese manners; namely, in carefully withholding from the view of the Europeans their women, though the latter did not appear otherwise to be very closely confined. The practice of polygamy, which prevails in China, has no place here, and, the English were told, was even held in abhorrence. From the free intercourse also of the different sexes, the parties had opportunities of being acquainted before marriage.

One of the most remarkable facts mentioned by Captain Hall is, that the natives of these islands were unacquainted with the use of fire-arms. From all that the English could observe, they were even ignorant of the use of money; and though those amongst the natives who had visited China must have seen the currency of that country, yet none of them showed any desire to possess Spanish dollars or gold coins, nor could it ever be learned whether they were in possession of any common medium of exchange. With regard to their want of arms, it is supposed by Mr Macleod, that the Chinese, after conquering, had disarmed them. The musketry and cannon of the English were objects of great wonder to them; and when they saw Captain Maxwell bring down a bird on the wing, they were shocked and terrified, and requested that fire-arms should not be again brought into the island. When Napoleon was informed, at St Helena, that these people had neither arms nor money, he ridiculed the idea as incredible and absurd, and affirmed that the English had been imposed on. The result justified his penetration. These people are well acquainted with both; and it is now known that, notwithstanding all their fair seeming, they are about the most remorseless pirates in the Yellow Sea. In their intercourse with our people, however, they were remarked for their honesty; insomuch, that though they were freely admitted on board of the English ships, and many valuable articles were often in their way, yet nothing was ever missed.

They appear to live on social and friendly terms with one another, and have frequently pic-nic parties in the fields, the dinner being carried about in little japanned boxes, with sliding drawers, fastened to the end of a bamboo. They entertained the English at dinner; and the meal consisted of hard-boiled eggs coloured and sliced, fish dried in butter, sliced junk smoked, sliced pig's liver; then came tea, which was succeeded by an unpalatable dish of coarse, soft, black sugar, wrapped up in unbaked dough. Cakes in various shapes, with something like cheese, completed the entertainment; the intervals being filled up with drinking sackee, and with smoking.

The Loo-chooans appear to have made no progress in science or literature, though several individuals amongst them were distinguished by the English for their intelligence, and turn for inquiry. Their language is a dialect of the Japanese; but they have Chinese books, which are studied by the learned. Their religion seems to resemble the superstition of China; but it is remarkable that the order of priests, who are generally objects of veneration in all countries, are here considered as an inferior caste. All the science of these islanders is derived from the Chinese. Their practice of medicine is also Chinese; and they generally administer to their patients roots, seeds, and dried flowers of the country. The capital of Great Loo-choo, and of the archipelago, is situated five miles from its port of Napakiang. The English were not allowed to approach it, but saw it from a distance, beautifully situated on the top of a hill; the houses, intermingled with the trees, rising above one another, and the royal palace above the whole. When the English left these islands, the natives professed the most affectionate regard for them, and expressed (with what sincerity the reader may judge) the deepest regret at their departure. Long. of the capital of the Great Loo-choo, 127. 52. 1. E. Lat. 26. 14. N.

LOOF, the after-part of a ship's bow, or that part of her side forward where the planks begin to be incurvated into an arch as they approach the stem.

LOOK-OUT, in nautical language, a watchful attention to some important object or event which is expected to arise from the actual situation of a ship with reference to other objects. It is principally used in navigation when there is a probability of danger from the real or supposed proximity of land, rocks, or enemies; in short, whatever peril she may encounter through inattention, but which might be avoided by a prudent and necessary vigilance.

LOOKIANG, a river in the Burman dominions, formerly supposed to be a tributary of the Irrawuddy, with which it has no connection. It is called Thaluayn in the Ava territories, and falls into the sea at Martaban.

LOOKING-GLASSES are plain mirrors of glass, which, being impervious to the light, reflect the images of things placed before them. See MIRROR and OPTICS.

LOOL, in *Metallurgy*, a vessel prepared to receive the washings of ores of metals. The heavier or more metallic parts of the ores remain in the trough in which they are washed; the lighter and more earthy run off with the water, but settle in the lool.

LOOM, the weaver's frame, a machine by which many distinct threads are woven into one piece. Looms are of various structures, accommodated to the various kinds of materials to be woven, and the various modes of weaving them, namely, for woollens, silks, linens, cottons, cloths of gold, and other works, as tapestry, ribands, stockings, and other articles, each of which will be found under its proper head. The weaver's loom-engine, otherwise called the

Dutch loom-engine, was brought from Holland to London about the year 1676.

Loom, at sea. If a ship appears big when at a distance, they say she looms, or appears a great sail. The term is also used to denote the indistinct appearance of any other distant objects.

LOONGHEE, a town of the Burman empire, situated on the east side of the Irrawuddy. Long. 19. 55. E. Lat. 19. 41. N.

LOOP, in the iron-works, is a part of a sow or block of cast iron broken or melted off from the rest, and prepared for the forge or hammer. The usual method is, to break off the loop of about three quarters of a hundredweight. This loop is taken up with slinging-tongs, and beaten with iron sledges till it be brought to a square mass of about two feet long, which is called a bloom.

LOP, a lake of Central Asia, situated upon the western side of the great desert of Shamo or Cobi, which lies between it and China. It has on its banks a city of the same name, on the great caravan road from Cashgar to China, of which the present state is not accurately known. According to Marco Polo, the caravans usually stop here, and prepare for crossing the formidable desert which lies before them.

LOPEZ de Vega. See Vega.

LORARII, amongst the Romans, officers whose business it was, with whips and scourges, to compel the gladiators to engage. The *lorarii* also punished slaves who disobeyed their masters.

LORCA, a city of Spain, in the province of Murcia. It is situated on a small river called the Sangonera, which is frequently dry. The soil is excellent for producing wheat, barley, olives, and fruits, but frequently fails from want of water, an evil which was attempted to be remedied by the construction of dykes in order to retain the streams when they are abundant; but, in 1803, these banks were burst by an unusual weight of water, the lands below were temporarily inundated, and since then they have at times felt the great evil of want of water. The city has nine parish churches, ten monasteries, 21,866 inhabitants, fourteen saltpetre houses, with a house for preparing soda; and it carries on a great deal of trade through the harbour of Aguilas, which is eleven and a half miles distant from it.

LORD, a title of honour, given to those who are noble either by birth or by creation. The title is also by courtesy given to all the sons of dukes and marquises, and to the eldest sons of earls; and it is likewise a title of honour bestowed on those who are honourable by their employment, as Lord Advocate, Lord Chamberlain, Lord Chancellor, and the like. The word is Saxon, but abbreviated from two syllables into one; for it was originally *Hlaford,* which by dropping the aspiration became *Laford,* and afterwards by contraction *Lord.* "The etymology of the word," says Coates, "is well worth observing; for it was composed of *hlaf,* a loaf of bread, and *ford,* to give or afford; so that *Hlaford,* now *Lord,* implies a giver of bread, because, in those ages, such great men kept extraordinary houses, and fed all the poor; for which reason they were called *givers of bread,* a thing now much out of date, great men being much fonder of retaining the title than of observing the practice for which it was first given."

Lords, House of, one of the three estates of parliament, and composed of the Lords Spiritual and Temporal.

1. The *Spiritual Lords* consist of the archbishops and bishops. Though these lords are in the eye of the law a distinct estate from the lords temporal, and are so distinguished in our acts of parliament, yet in practice they are usually blended together under the name of The Lords; they intermix in their votes, and the majority of such intermixture joins both estates. From the want of a separate assembly, and a separate negative on the part of the prelates, some writers have argued very cogently, that the lords spiritual and temporal are now in reality only one estate; and this is unquestionably true in every effectual sense, though the ancient distinction between them still nominally continues. For if a bill should pass their house, there is no doubt of its validity, though every lord spiritual should vote against it (of which Selden and Sir Edward Coke give many instances); as, on the other hand, it would doubtless be equally good if the lords temporal present were inferior to the bishops in number, and every one of those temporal lords gave his vote to reject the bill, though Sir Edward Coke seems to doubt as to this.

2. The *Temporal Lords* consist of all the peers of the realm (the bishops not being in strictness held to be such, but merely lords of parliament), by whatever title of nobility distinguished; dukes, marquises, earls, viscounts, and barons. Some of these sit by descent, as do all ancient peers; others by creation, as do all new-made ones; others, since the union with Scotland and Ireland, by election. The Lords have a right to be, and constantly are, attended by the judges of the courts of King's Bench and Common Pleas, and such of the Barons of the Exchequer as are of the degree of the coif, or have been made serjeants at law; as likewise by the king's learned counsel, being serjeants, and by the masters of the court of Chancery, for their advice in point of law, and for the greater dignity of their proceedings. The secretaries of state, with the attorney and solicitor general, also used to attend the House of Peers, and have to this day their regular writs of summons issued out at the beginning of every parliament, *ad tractandum et consilium impendendum,* though not *ad consentiendum;* but whenever they have been members of the House of Commons, their attendance here has, for a long period, been dispensed with. Another privilege is, that every peer, by license obtained from the king, may make another lord of parliament his proxy, to vote for him in his absence; a privilege which a member of the other house can by no means exercise, as he is himself but a proxy for a multitude of other people. Each peer has also a right, by leave of the house, when a vote passes contrary to his sentiments, to enter his dissent upon the journals of the house, with the reasons for such dissent, which is usually styled his protest. All bills likewise, which may in their consequences affect in any way the rights of the peerage, are by the custom of parliament to have their first rise and beginning in the House of Peers, and to suffer no changes or amendments in the House of Commons.

LORD Howe's Group, a cluster of islands in the Pacific Ocean, discovered by Captain Hunter in 1791. Of these, thirty-two were counted from the mast-head. They are situated in about long. 159. 24. E. and lat. 5. 30. S.

LORDOSIS (of λορδος, *bent inwards*), in medical writings, a name given to a distempered state of the spine, in which it is bent inwards, or towards the anterior parts. It is used in opposition to *gibbous,* or *hump-backed.*

LORETTO, a city of the delegation of Macerata, in the papal dominions, in Italy. It is situated at the spot where the river Musone falls into the sea. It is surrounded with walls and ditches, has a cathedral, and several other churches, and contains about 8000 inhabitants. It is remarkable for the *Santa Casa,* or sacred house, which is affirmed to have been miraculously brought to this place in 1294, and over which a large church has been constructed in order to preserve it. It is an object of veneration with many Catholics, and is visited by great numbers of pilgrims. The subsistence of the people mainly depends on this object, and in making rosaries, crucifixes, medallions, and other articles for the gratification of pious visitors. Its wealth was dissipated during the French revolution, but it has since accumulated treasures, though not with the rapidity of former times. Long. 13. 29. 45. E. Lat. 43. 27. N.

Loretto, a town of the kingdom of Naples, in the province of Abbruzzo Citeriore, containing 3500 inhabitants.

LORGUES, a city of France, in the department of the Var, and arrondissement of Draguignan. It contains 5000 inhabitants, who employ twelve mills in crushing olives, and produce a very large quantity of the best oil. Long. 6. 31. E. Lat. 43. 29. N.

LORICA, a cuirass, brigantine, or coat of mail, in use amongst the Roman soldiers. It was generally made of leather, and its name is supposed to be derived from *lorum.* The *loricæ* were set with plates of metal in various forms; sometimes in books or rings like a chain, sometimes like feathers, and sometimes like the scales of serpents or fishes, to which plates of gold were frequently added. There were other lighter cuirasses, consisting only of numerous folds of linen cloth, or of flax, made strong enough to resist weapons. Such soldiers as were rated under a thousand drachms, instead of the *lorica* now described, wore a *pectorale.* The Roman *lorica* was made like a shirt, and defended the wearer both before and behind, but was so contrived that the back part could be occasionally separated from the front. Some of the *loricæ* were made of cords of hemp or flax, close set together; and hence they are called *thoraces, bilices, trilices,* and so on, from the number of the cords fixed one upon another; but these were used rather in hunting than in the field of battle.

LORIOL, a town of France, in the department of the Drome, and arrondissement of Valence, situated on the river Drome, over which is an extraordinary bridge, with an arch in the centre of eighty-four feet in span. It contains 390 houses, and 2460 inhabitants.

LORNE, a division of Argyleshire, in Scotland, which gives the title of marquis to the Duke of Argyll. See ARGYLESHIRE.

LORRAINE. See FRANCE.

LOSTWITHIEL, a borough and market town of the county of Cornwall, in the hundred of Powder, 246 miles from London. It stands on the river Fowey, but the harbour is nearly choked up. A stannary court is held here, and a market on Saturday. It formerly returned two members to parliament, chosen by the corporation, but it has been deprived of that privilege by the reform law. Near to it is the fine seat of Bocconnoc, belonging formerly to Lord Camelford, now to Lord Grenville. The population amounted in 1801 to 743, in 1811 to 825, in 1821 to 933, and in 1831 to 1548.

LOT, a department of France, formed out of the division of Quercy, in the ancient government of Guienne. It extends in north latitude from 44. 14. to 45. 2. and in east longitude from 0. 52. to 2. 2., being in extent 2156 square miles, or 398,406 hectares. It is bounded on the north by the department of the Corrèze, on the east by Cantal and Aveyron, on the south by Tarn-Garonne, and on the west by Lot-Garonne and Dordogne. It comprises three arrondissements, twenty-nine cantons, and 345 communes, and is peopled by 263,500 persons. It is an undulating district, with hills of moderate height, having between them valleys of great fertility. The soil is generally dry and somewhat rocky, but is covered with a coat of mould, deepest in the valleys, which produces excellent corn, so that the surplus of grain is greater than in any other of the departments of France. The several fruits, especially plums, chestnuts, and walnuts, are raised in great abundance; but the chief fruit is the grape, which is grown extensively on the hills. The wine has great reputation, both from being uninjured by transportation, and by keeping good for a long time. The best grows in the arrondissement of Cahors, whence about 60,000 pipes are sent, some of them to Bordeaux. Much brandy also is made, as well as vinegar, and both enjoy great reputation. The agriculture is well conducted, and, besides corn, affords good crops of pulse, hemp, flax, and saffron. The breed of black cattle is very good, and the flocks of sheep are numerous; the quality of the wool having been much improved of late years by crossing their own with Merinos from Spain. The only mines are some few of iron; but the quarries yield mill-stones, alabaster, marble, limestone, and fullers' earth, in great abundance. The manufactures are inconsiderable, consisting of woollen and linen cloth, some hardware, paper, and leather. The department elects three deputies to the legislative body. The capital is the city of Cahors.

LOT AND GARONNE, a department of France, formed out of those parts of the ancient government of Guienne denominated Condomois and Agenois. It extends in north latitude from 43. 58. to 44. 45. and in longitude from 0. 21. east, to 0. 49. west, containing 2249 square miles, or 532,640 hectares, of which 306,720 are under the plough, 65,320 are vineyards, 59,640 are woods and forests, 32,726 are meadows, 52,704 are uncultivated, 6816 are marshes, and the remainder are the courses of rivers and the sites of towns and villages. It is bounded on the north by the departments of the Gironde and of the Dordogne, on the east by those of the Lot and the Tarn-Garonne, on the south by Gers, and on the west by the Gironde. It is divided into four arrondissements, twenty-nine cantons, and 435 communes, and contains 326,850 inhabitants, of whom about 30,000 are Protestants, and the remainder adhere to the Roman Catholic church. It is a lofty plain, intersected with deep valleys, the hills bounding which are covered with vines, whilst the bottoms have streams bordered by fertile meadows. The two chief rivers, the Lot and the Garonne, are navigable for barges the whole length of the department, and receive the waters of numerous tributary streams. The soil is generally fertile, and though, from attachment to old and slovenly customs, agriculture is ill conducted, as much corn is produced as enables one fourth of the crops to be disposed of to the neighbouring departments. The land is chiefly occupied by small farmers, who pay their rent by delivering half the crops to the owner. Besides corn, much hemp of excellent quality is raised, and also some flax. A vast quantity of fruit is produced. The wine is generally of a medium quality; but some of great estimation is made in Thezac, Perigord, Lavocal, and Clairac. The forests, besides fire and building wood, yield tar, turpentine, and pitch, and considerable quantities of cork. A great number of bees are kept, which make much honey and wax; and it is said that two millions of geese are maintained. The only mines are those of iron, which furnish yearly about 1400 tons, the greater part of which is manufactured for home consumption into various kinds of hardware. There are some manufactures of sailcloth and other linens, and of woollens, leather, glass, paper, and snuff from tobacco grown in several parts. One of the most extensive employments is that of cork-cutting, which is said to supply more than thirty millions of corks. The members chosen for the legislative body are three. The capital is the city of Agen.

LOTHIAN, a name given to three counties of Scotland, Haddingtonshire, Edinburghshire, and Linlithgowshire; otherwise called *East, Mid,* and *West* Lothians. See the articles on these different shires.

LOTION is, strictly speaking, such washing as concerns beautifying the skin, by cleansing it of those deformities which are thrown out upon it by distempered blood.

LOTION, in *Pharmacy,* denotes a preparation of medicines, by washing them in some liquid, either made very light, so as to take away only the dregs, or sharp, so as to penetrate them, in order to clear them of some salt or corrosive spirit, as is done to antimony, precipitates, magisteries, and the like, or intended to take away some foulness or ill quality, and communicate some good one.

LOTOPHAGI, in *Ancient Geography,* a people of the

Regio Syrtica (so called from their living upon the lotus), inhabiting the country between the two Syrtes, from the Cinyphus to the Triton. The lotus was said to be so luscious a food as to make strangers forget their native country.

LOTTERY, a kind of public game at hazard, in order to raise money for the service of the state, being with us appointed by the authority of parliament, and managed by commissioners appointed by the Lords of the Treasury for that purpose. It consists of several numbers of blanks and prizes, which are drawn out of wheels, one of which contains the numbers, and the other the corresponding blanks or prizes.

The Romans invented lotteries in order to enliven their Saturnalia. This festival began by the distribution of tickets which gained some prize. Augustus made lotteries which consisted of things of little value; but Nero established some for the people, in which a thousand tickets were distributed daily, and several of those who were favoured by fortune got rich by means of them. Heliogabalus invented some very singular ones, in which the prizes were either of great value or of none at all; one gained a prize of six slaves, and another of six flies; some got valuable vases, and others vessels of common earth.

The first English lottery which we find mentioned in history was drawn in the year 1569. It consisted of 40,000 lots, at 10s. each lot. The prizes were plate; and the profits were to go towards repairing the havens of the kingdom. It was drawn at the west door of St Paul's cathedral. The drawing began on the 11th of January 1569, and continued incessantly, day and night, until the 6th day of May following. (Maitland, vol. i. p. 257.) There were then only three lottery-offices in London. The proposals for this lottery were published in the years 1567 and 1568. It was at first intended to have been drawn at the house of Mr Dericke, her majesty's jeweller; but it was afterwards drawn as above mentioned.

In 1748, Dr Rawlinson showed the Antiquarian Society "A proposal for a very rich lottery-general without any blankes, contayning a great number of good prizes, as well of redy money as of plate and certain sorts of merchandizes, having been valued and prised by the commandment of the queene's most excellent majestie's order, to the intent that such commodities as may chance to arise thereof, after the charges borne, may be converted towards the reparations of the havens and strength of the realme, and towards such other public good workes." He then goes on to say, "The number of lotts shall be foure hundred thousand, and no more; and every lott shall be the summe of tenne shillings sterling, and no more. To be filled by the feast of St Bartholomew. The shew of prizes are to be seen in Cheapside, at the sign of the Queene's Armes, the house of Mr Dericke, goldsmith, servant to the queene."

In the reign of Queen Anne, it was thought necessary to suppress lotteries as public nuisances. Since that time, however, they have been licensed by act of parliament, under a variety of regulations. The act passed in 1778 restrains any person from keeping an office for the sale of tickets, shares, or chances, or for buying, selling, insuring, or registering, without a license; for which license each office-keeper must pay L.50, to continue in force for one year, and the produce to be applied towards defraying the expense of the lottery. And no person is allowed to sell any share or chance less than a sixteenth, on the penalty of L.50. All tickets divided into shares or chances are to be deposited in an office, to be established in London by the commissioners of the Treasury, who are to appoint a person to conduct the business thereof; and all shares are to be stamped by the said officer, who is to give a receipt for every ticket deposited with him. The numbers of all tickets so deposited are to be entered in a book, with the names of the owners, and the number of shares into which they are divided. All tickets deposited in the office are to remain there three days after the drawing. Any person keeping an office, or selling shares, or who shall publish any scheme for receiving moneys in consideration of any interest to be granted in any ticket in the said lottery, without being in possession of such ticket, shall forfeit L.500, and suffer three months imprisonment. No business is to be transacted at any of the offices after eight in the evening, except on the evening of the Saturday preceding the drawing; and no person is to keep any office for the sale of tickets in Oxford or Cambridge, on penalty of L.20. Before this regulating statute was passed, there were upwards of four hundred lottery-offices in and about London only; but the number for all Britain, as appears by the list published by authority, afterwards amounted to not more than fifty-one. Subsequently, however, they increased greatly in number.

Some further regulations to prevent the frauds committed by insurances were made in 1793. In 1808 the reports of a committee of the House of Commons disclosed a dreadful scene of vice and misery brought on by lotteries, and recommended their abolition, or at least that they should be put under other regulations. The gross sum received by government from the lottery was estimated at L.750,000 per annum, of which L.500,000 was for tickets, and the remainder for postages, stamps, &c. At length, lotteries, which had proved eminently prejudicial to public morals, by fostering among the people a propensity to gambling, and which, in a fiscal point of view, had yielded but a trifling amount of revenue to the state, were put an end to by a Treasury minute, which provided that, from and after the 18th of October 1826, they should cease and determine; and this abolition was accompanied with a prohibitory declaration against all attempts on the part of individuals to revive or continue them in any mode or form whatsoever. Some years ago, however, a bill was brought into parliament for disposing, in this sort of way, of some property in Glasgow; and, as the obnoxious denomination of lottery was carefully excluded, general terms alone being employed in the bill, it accidentally escaped notice, and thus passed into a law. But it is well understood that this took place *per incuriam*, and that any future attempt of a similar description will certainly prove unsuccessful.

LOUDEAC, an arrondissement of France, in the department of the North Coasts, extending over 624 square miles, and containing a population of 89,500 persons. It is divided into nine cantons and fifty-five communes. The capital is a town of the same name, which contains 6000 inhabitants, chiefly employed in branches of the linen trade.

LOUDON, an arrondissement in the department of the Vienne, in France, extending over 379 square miles. It contains four cantons, divided into sixty-seven communes, and is inhabited by 33,400 persons. The capital is the city of the same name, which occupies a mountainous situation. It is well built, and contains 860 houses, with 5600 inhabitants, who are occupied in tanneries, and in making thread-lace, serges, and other thin woollen goods. Long. 0. 3. W. Lat. 47. 2. N.

LOUER, a town of Hindustan, belonging to the Mahrattas, in the province of Aurungabad, situated upon the banks of the Girah River. It is in long. 74. 27. E. lat. 20. 25. N.

LOUGH NEAGH, a loch or lake of Ireland, situated in the counties of Armagh, Down, Derry, and Antrim, in the province of Ulster. This lake is twenty miles in length, and varies from eight to twelve miles in breadth. The area of this lake is computed at 100,000 acres.

Lough *Strangford*, a lake of Ireland, situated in the county of Down and province of Ulster. It was formerly known by the name of *Lough Cone* or *Lough Coyne*. It is a deep bay or inlet of the sea, about seventeen miles long and four or five broad. It reaches west as far as Downpatrick, and north as far as Comber and Newton, and by computation covers 25,775 acres Irish plantation measure.

LOUGHBOROUGH, a market-town of the county of Leicester and hundred of West Goscot, 108 miles from London, and situated on the river Soar. It has considerable trade, arising from being on a navigable canal, and on the great north road. The market is held on Thursday. The population amounted in 1801 to 4546, in 1811 to 5400, in 1821 to 7365, and in 1831 to 10,800.

LOUHANS, an arrondissement belonging to the department of the Saone and Loire, in France, extending over 605 square miles, and peopled by 78,300 persons. It is divided into eight cantons, and eighty-three communes. The chief place is a city of the same name, situated on an island formed by the junction of three small rivers. It contains 330 houses and 3250 inhabitants, who manufacture linen and woollen goods, and carry on some transit trade between Lyons and Switzerland.

LOUIS, or St Louis, *Knights of*, the name of a military order in France, instituted by Louis XIV. in 1693. Their colours were of a flame colour, and passed from left to right; the king was their grand master. There were in the order eight great crosses, and twenty-four commanders; but the number of knights was not limited. At the time of their institution, the king charged his revenue with a fund of 900,000 livres for defraying the pensions of the commanders and knights.

Louis d'Or, a French coin, first struck in the year 1640, under the reign of Louis XIII. See the article Money. By the French mint regulations it was at length made equal to twenty-four livres, or L.1 sterling. This, however, was underrating it in respect of silver; and hence, as every one preferred paying his debts in the overvalued coin, silver became the principal currency of France, the gold coins being either sent to the melting-pot, or exported. In Britain the process was reversed. Gold having, for a long period, been overvalued by our mint in respect of silver, it became the principal currency of the country.

LOUISIADE, an archipelago in the Eastern Seas, consisting of a number of islands of different sizes, interspersed with dangerous shoals and reefs, which chiefly received names from the French during their voyage in search of La Pérouse in 1793. Some of these islands are fertile and populous, and their inhabitants are a warlike race.

LOUISIANA, one of the United States of North America, is bounded on the east by the state of Mississippi, on the west by the Sabine River, on the north by the Arkansas territory, and on the south by the Gulf of Mexico. It extends from longitude 89. to 94. 5., and its extreme southern point is in latitude 28. 56. whilst its northern limit is in latitude 33. The average length is about 240 miles, and the mean breadth rather more than 200 miles, the area being estimated at 48,220 square miles. The surface of Louisiana presents great diversity of appearance, and no state in the union possesses a greater quantity of the very finest land. It includes all the varieties, from the most recent and still periodically inundated alluvial flats, to elevations which approach the magnitude of mountains; every quality of soil, from the most productive to the most sterile, from unwooded plains to dense and almost impenetrable forests. The southern part of this state, from Lake Borgne to Sabine River and from the Gulf of Mexico to Baton Rouge and Red River, is an alluvial tract of country, extending about two hundred and forty miles in length by from seventy to one hundred and forty in breadth. It is intersected by numerous rivers, bays, creeks, and lakes, which divide the country into a great number of islands. Three fourths of the state are destitute of any elevation which deserves the name of a hill. The pine woods generally have a surface of a very particular character, rising into fine swells, with table surfaces on the summit, and valleys from thirty to forty feet deep. But they in no part present the aspect of a range, and are scattered over the country like the waves of an agitated sea. The alluvial soil is level, and the swamps are dead flats. The vast prairies, which constitute a large portion of the state, present a surface as level as a frozen lake. With the exception of the shaking prairies, they are higher and drier than the savannahs of Florida. A range of hills commences by gentle undulations in Opelosas, rises gradually, and diverges towards the river Sabine. In the vicinity of Natchitoches it preserves a distance intermediate between the Sabine and Red Rivers, and increases in elevation to the western part of the state. A second line of hills, not far from Alexandria, commences on the north side of Red River, and separating between the waters of that river and Dudgemony, unites with another chain of elevations which bound the alluvial plains of the Washita as bluffs, gradually diverging from that river as they pass beyond the western limits of the state. There are likewise some considerable hills beyond the Mississippi, and in some other parts the country is high; but, generally speaking, Louisiana is one immense plain, divided into pine woods, prairies, swamps, and hickory and oak lands. The pine woods have almost invariably a poor soil. The greater proportion of the prairies is second-rate land, and some of them are even sterile. A few, however, in Opelosas, and those of Attakapas, possess great fertility. They are in general more level than those of the upper country. A very considerable extent of them has a cold clayey soil, with a hard crust near the surface. In other places the soil is of inky blackness, and in the hot and dry season it cracks into fissures of some inches in width. A considerable belt of these prairies, near the gulf, is low, marshy, and in rainy weather inundated. The bottoms are generally rich, but in very different degrees. Those of the Mississippi and Red Rivers are particularly so, and the vegetation there is remarkable for its size and luxuriance. The cotton on fresh lands of the richest quality reaches the size of a considerable shrub. The bottoms of Red River possess extraordinary fertility, and the lower courses of this stream constitute the paradise of cotton planters. The soil is said to derive its fertility from a portion of salt which is intimately mixed with it, and from its peculiar friability; and the darkish red colour which it bears is to be traced to the presence of the red oxide of iron. All the branches of Red River, and they are very numerous, partake of the character of the main stream. The other parts of Louisiana which have the richest soils are, the island of New Orleans, a narrow neck of land, insulated by various lakes and rivers. About one third of this neck is under cultivation, the other two thirds being swamp. This tract is the finest part of the rich country called the *Coast*, which is that part of the bottom of the Mississippi commencing with the first cultivation above the Balize, about forty miles below New Orleans, and extending one hundred and fifty miles above it. It is from one to two miles in breadth; and a richer tract of land of the same extent cannot be found on the globe. It is secured by an embankment, called a levee, from six to eight feet in height, and for the most part sufficiently broad to afford room for a fine road. Above the levee, on the east bank of the river, are situated the parishes of Baton Rouge and East and West Feliciana. The latter parish is pleasantly diversified with hills and valleys, and belonging to it are the richest planters and the best plantations in the state, in some of which there are from five to eight hundred acres under cultivation. West of the Mississippi there are some tracts of soil very fertile, and here the sugar-cane thrives well. A considerable portion of Attakapas is of great fertility, as are smaller portions of Opelosas, which is, however, best adapted for a grazing country. Near the Red River there occur several tracts of very fertile soil, on parts of which the richest cotton is produced. The lands on the Washita River are black, like those on the Mississippi; and the alluvions on the lower courses of this stream furnish an admirable soil for cotton, and other productions that require the same climate.

A very great proportion of the surface of this state is covered with prairies, almost all of which are so associated with one another as to form a family, the natural connection of all the branches being easily traced. The first that occur west of the Mississippi are those which are included under the general name of Attakapas; a term implying "man-eater" in the language of the savages who formerly inhabited it, and who are said to have been cannibals. It is an immense plain of grass, stretching from the Atchafalaya on the north to the gulf on the south. It is extremely fertile, innumerable herds of cattle and horses graze upon it, and at intervals are scattered over its immense surface the houses of the agriculturists. To the west of this prairie occurs that of Opelosas, still larger than the former, and computed to contain nearly 8000 square miles. It is divided, by various natural boundaries or obstructions, into a number of prairies, which have separate names and marks of distinction. The soil, though occasionally very fertile, is less so than that of Attakapas; but this deficiency is compensated by the greater salubrity of the climate, which is reckoned the healthiest in the state. There are here very considerable cotton plantations, and some of indigo; and the parish, which bears the same name, is one of the most populous in the state. Bellevue prairie is situated partly in Opelosas, partly in Attakapas, and, as its name imports, affords a delightful prospect. Calcasiu and Sabine prairies are names descriptive of the different forms, shapes, and openings of this continuous line of prairies, as it stretches along the settlements from the Plaquemine to the Sabine. Some of them are of great extent, and they all possess nearly the same characteristics. They are generally so level as to appear to the eye a perfect plain; but there occasionally occur swells and declivities, such as are sufficient to carry the water from them. The margin which borders on the gulf is commonly a wet marsh, covered with a luxuriant growth of tall reedy grass called cane-grass. In various parts of these prairies there are islands of timber lands. Wherever a bayou or stream crosses the prairie, it is marked with a fringe of timber; and here the soil is invariably rich, as well as at the points of the prairie; but towards the Sabine it is less so. Attakapas is the first and most fertile, and that of the Sabine the last and most sterile. Beyond Opelosas prairie most of the people subsist by rearing cattle, sheep, horses, and mules. Many of the horses are of the Andalusian and Numidian breed; and the cattle are excellent, though slenderly formed. Numbers of the inhabitants are French, and though often opulent, from habit and inclination they adhere to the simplicity of pastoral life and primitive nature. Thousands of cattle range the plains, there is a rustic abundance of every thing, and the land abounds in milk and honey. There are various other prairies, but as they are of less importance than those above enumerated, and moreover possess similar general features, they do not require any particular description.

Wheat and rye do not flourish here in general, but oats and barley succeed well; and maize grows luxuriantly on the alluvions and rich lands. The sweet potato, *convolvulus batatas*, in the sandy soil attains its utmost perfection. They are of different species, and occasionally of a very large size, but all are extremely nutritive, and raised with ease in great abundance. The Irish potato is not so easily raised, and is only cultivated for eating during the early part of summer. Garden vegetables generally appear to have no assignable limit upon a soil so varied, and in a climate so near the tropics. It may seem almost incredible that horticulture should be neglected in Louisiana, yet such is the case; and the fact seems the more unaccountable, when it is considered that some individual gardens present what would appear an irresistible temptation. The pumpkin and melon tribe flourish in this climate. All the northern fruits come to perfection, with the exception of apples. The apple-tree covers itself with blossoms and fruit, which, before it ripens, shows a black speck, decays, and falls. Different kinds of figs grow in the greatest abundance, and the tree would appear to attain its largest size in this quarter; but, although growing spontaneously, it is only to be found on a few farms. Along the whole shore of the gulf, and in some other places, the orange-tree, sweet and bitter, flourishes, and the fruit is of the finest quality. The cultivated vine flourishes abundantly; and wild grapes, such as the summer, winter, fox, muscadine, and pine-wood grape, are abundant. Berries are neither so common nor so good as in the north, but various kinds of wild fruit are common in the woods. There are an immense number of wild and cultivated flowering shrubs, which flourish in this region; and the abundance of mulberry trees holds out a prospect that the culture of silk will ere long form one of the branches of trade in this state. The timber-trees on the bottoms are willow, cotton-wood, honey-eye locust, pawpaw, and buck-eye; on the rich uplands, elm, cucumber, ash, hickory, mulberry, black walnut, with abundance of grape vines; and on the second rate, or sandy uplands, white, pitch, and yellow pines, and various kinds of oak. As yet agriculture is only in its infancy, the principal object being not to produce a great variety of crops, but to obtain the greatest amount of the staple productions. Sugar and rice are the staples of the state in general south of 30°, and cotton north of that parallel; the latter, however, is extensively cultivated in every part of the state. Sugar-cane is a very rich and abundant article of growth in Louisiana. It requires the richest soil, the mould of which should at least be a foot deep. There are three or four varieties or species, as the African, the Otaheitan, the West Indian, and the riband cane. The Otaheitan grows luxuriantly, and ripens considerably earlier than the West Indian; but it is said to contain saccharine matter, in comparison with the other, only as two to three. The riband cane is a new and beautiful species, which possesses the advantage of not requiring so long a season for ripening. Throughout the state the planters are turning their attention to the cultivation of the sugar-cane, and nothing yields so rich a harvest. The rice is remarkably fair, and yields abundantly. There is a great extent of land favourable for the production of the upland rice; and no limit can be assigned to the amount which might be raised. The cotton cultivated here is an annual plant, growing in the rich lands more than six feet in height, and the larger stalks of the size of a man's arm, throwing out a number of branches, on which form large and beautiful whitish-yellow blossoms. It is planted from March till the middle of May, in drill rows, six feet apart. The kinds of cotton cultivated are, Louisiana, green seed or Tennessee, and recently Mexican cotton. The green seed is not so fine a staple, but it is less subject to the destructive malady called the rot. The Mexican is of a finer staple, yields more abundantly, and has not hitherto suffered from rot. It is being commonly adopted, and the importation of seed from Tampico and Vera Cruz is becoming a considerable business. Sea Island cotton grows well upon grounds that have been exhausted by the

Louisiana.

continued cultivation of the other kinds. All the species exhaust the soil; but the seeds, which accumulate in prodigious quantities around the gins, furnish an admirable manure, which supplies the deficiency of nutriment. Attempts have been made to cultivate the tea plant; and benne, which yields an oil similar to that of olives, succeeds well. Indigo was formerly a prime object of attention amongst the planters, but the cultivation of it has been in a great measure abandoned. The finest tobacco is raised, but it is not so profitable as sugar and cotton, although that which is cultivated in the vicinity of Natchitoches is said to equal the tobacco of Cuba. Louisiana produces annually an average crop of more than 100,000 hogsheads of sugar, and five millions of gallons of molasses. It is to this individual branch of agriculture that the prosperity of the Union in general, and the west in particular, has in a great measure been attributed. Such is a sketch of the agriculture of Louisiana. We shall now describe the divisions of the state, and the principal towns belonging to it.

The state of Louisiana is, for the better arrangement in the choice of the legislature, divided into twelve counties These are,

The county of Orleans,
...... German Coast,
...... Acadia,
...... Iberville,
...... Lafourche,
...... Point Coupee,
Rapides.
Natchitoches
Concordia.
Ouachita.
Opelosas.
Attakapas.

This division was made in 1812, when the constitution by which the state is governed was first framed.

[1] From New Orleans.

[2] From Washington.

New Orleans, the commercial capital of the state, and the emporium of western commerce, is situated on the east bank of the Mississippi, in a bend so deep and sinuous, that the sun rises to the inhabitants of the city from the opposite shore, in north latitude 29. 57. and in longitude 98. 8. west from Greenwich. It is nearly intermediate between Boston and Mexico, although the passage from New Orleans to Vera Cruz is much shorter by sea than to Boston. It consists of the old city properly so called, which is built in the form of a parallelogram, of which the longer sides are 1320 yards in length, and the shorter, or the depth of the city towards the swamp, 700 yards. No city on the globe possesses so great natural advantages for a commercial capital as New Orleans. It has an easy communication with the ocean; and above the city there are 20,000 miles of navigation by means of the Mississippi and its numerous tributaries, whilst various bayous connect it with different parts of the state. By a basin and canal it communicates with Lake Ponchartrain, the lakes thence to the Gulf of Mexico, the opposite Florida shore, with Mobile, Pensacola, and the whole gulf-shore east and west. There is also a railroad four and a half miles long between the city and Lake Ponchartrain. Seen from the harbour, New Orleans presents a striking panoramic view. The old city is divided into six squares, each square having a front of 319 feet in length, and being divided into twelve lots. Few of the streets are more than forty feet wide. Buildings of brick have now replaced the wooden structures of which the city was formerly composed. The French and Spanish styles of building predominate, and the houses are stuccoed externally. The public buildings are, the town-house, the hospital, the cathedral church of St Louis, the convent of Ursaline nuns, the barracks, the custom-house, the market-house, five banks with a capital of 4,000,000 of dollars, a government-house, district court of the United States, water-works, two theatres, and a Presbyterian and other churches. Several of these buildings, as the cathedral, are large, commodious, and handsome. The Fauxbourg of St Mary, and other new parts of the city, are built principally of brick, after the American style; and in general the city is gradually becoming American in all its characteristics. Between the city and the bayou St John, are the villages St Johnsburg and St Claud. The commerce of this city is immense, and constantly increasing. There are sometimes in the harbour 1500 flat boats at a time; and steam-boats arrive and take their departure every hour. No place in the United States has so much activity and bustle of commerce, crowded into so small a space, in the months of February and March. During the season of bringing in the cotton crop, whole streets are barricaded with cotton bales. The amount of domestic exports from this city exceeds twelve millions of dollars a year, being greater than that of any other city of the Union excepting New York, and nearly equalling that place. The greatest items which enter into this amount are sugar and cotton. From being placed in the midst of immense swamps, New Orleans is generally considered as unhealthy, but few towns in the United States have increased with greater rapidity. The market in general is cheap and abundant, and the productions of every climate find their way thither. This city necessarily exercises a very great moral influence over all the western country; and there is not a distinguished merchant, planter, or farmer, in the Mississippi valley, who has not made at least one trip to this place. The police of the city is at once mild and efficient, and the municipal and criminal courts are prompt in administering justice. A great portion of the inhabitants of New Orleans are of French and Spanish descent, and the French language is more used than the English. During the busy season, the manners, dresses, customs, and languages of every quarter of the globe are here exhibited. The means of education in this city are very limited compared with those of the other large cities of the United States, but there have been great improvements within the last few years; and, considering that one half of the people are slaves, the state of morals is better than might be expected. The following are some of the principal imports into New Orleans for the year 1829:—Bagging, 13,472 pieces; buffalo robes, 15,210 lbs.; cotton, 269,571 bales; corn in ears, 91,882 barrels; flour, 157,323 barrels; lard, 110,206 kegs; pig lead, 146,203 pigs; deer-skins, 6215 packs; tobacco, 29,432 hhds. The amount of cotton exported in the year ending the 30th of September 1830 was 354,024 bales. Nothing seems adverse to the growth of New Orleans except the unhealthiness of its climate; but, by draining and otherwise improving it, it will probably be rendered more healthy, and become one of the largest cities in the Union.

Donaldsonville, on the west side of the Mississippi, at the efflux of Lafourche, ninety miles above New Orleans, has a number of houses, and has been selected by the legislature as the place for the future political capital of the state. Baton Rouge is on the east side of the Mississippi, 140 miles above New Orleans. It is pleasantly situated on the last bluff that is seen on descending the river. The site is thirty or forty feet above the highest overflow of the river. The United States barracks here are built in a fine style, and are supposed to be amongst the handsomest and most commodious of the kind. There is a delightful prospect from the esplanade, including a great extent of the coast, with handsome houses and rich cultivation below, and commanding an extensive view over the back country to the east. The town consists of a number of French and Spanish houses, with several green squares, and contains 1200 inhabitants. St Francisville is a considerable village, of nearly the same size as Baton Rouge. A good way to the westward of this town is Jackson, which is the seat of an incipient college. On the opposite shore is Point Coupee, a wealthy French settlement. Galveztown is situated on Bayou Manshac, or Iberville, not far from where it enters Lake Ponchartrain. Alexandria, on Red River, seventy miles from the Mississippi, and 150 from the mouth of the river by its course, is situated on the south bank of the river, half a mile below the fall. It is central to the rich planting country of Bayous Rapide, Robert, and Bœuf. It is the seat of justice for the parish, has a bank, a number of stores, and respectable attornies and physicians, and issues a weekly paper. Vast quantities of cotton are exported from this place. The last town of any size towards the south-western frontier of the United States is Natchitoches, about sixty miles above Alexandria. The Spanish trade for a considerable distance into the interior of the Mexican state centres here, and it is the great thoroughfare for people going to and returning from these states. The trade from them consists chiefly in bars of silver, and in horses and mules. Manufactured goods, groceries, spirits, and tobacco, are sent in return. This is a very considerable and growing place, and is likely to become the largest town in the country, except New Orleans. It is beautifully situated on the bank of the river, and is at the head of the steam-boat navigation. A few leagues to the west of this town is the ancient Spanish town of Adayes, the inhabitants of which are all Spanish. There are some other places, but none of such importance as to demand particular mention.

The canal which connects the city of New Orleans with Lake Ponchartrain has already been mentioned. Where it terminates, at the north of the city, there is a convenient basin, excavated entirely by art, and large enough to contain a great number of vessels. Immense labour and expense were necessary to render the river navigable, especially at the mouth of the lake, where a large and impassable bar was removed, and large piles of wood driven into the sand to prevent it from forming again. A provision in the charter of this canal corporation allows them to extend it to the Mississippi.

The roads are for the most part good, but when they diverge to any distance from the rivers they are subject to inundation. Numerous railroads and canals have been projected; and there is no country in the world where nature has done more towards forming natural canals, which a little labour would complete by artificial extensions.

The country was first peopled by the French, but the Spaniards obtained possession of some parts, and established colonies in it. It was again conquered by the English, and many of the original settlers remained in the country. It was not admitted into the federal union until 1812. From the frequency of these conquests, and the number of settlers from different nations, the character of the inhabitants is different from that of those in most of the other states. The descendants of the French possess many characteristics of that people, and formerly lived in a state of pastoral simplicity. They are mild, vivacious, and polite. The American planters are high minded, social, irascible, and generous; much addicted to hunting, gambling, and dissipation. The people generally are volatile, gay, benevolent, and easily excited to joy or sorrow. Education was formerly at a very low ebb, but latterly ample and munificent appropriations have been made, each parish in the state granting eight hundred dollars annually for that purpose. The language generally spoken is French, but in a very corrupt state. The prevailing religion is Roman Catholic, there being only a few Baptists and Methodist societies, and one Presbyterian church, in the state.

The constitution differs in some minor points from those of the other western states. The senators are elected for a period of four years, one fourth vacating their seats annually; and they must possess a property worth 1000 dollars before they can be chosen. The representatives are elected for two years, and, to be eligible, must have property in the parish worth 500 dollars. The governor is elected for four years, with a salary of 7000 dollars annually, and cannot be chosen for the next term. A supreme and circuit court exercise the judiciary power, together with a municipal or parish court. Every free white man above twenty-one years is entitled to vote in the elections, provided he has been six months in the parish, and has paid taxes. In civil jurisprudence, this state has, with some modifications, adhered to that derived from France and Spain; but in criminal matters they have followed the English jurisprudence.

This state has an extensive, and, from its great natural advantages, rapidly increasing commerce. The quantity of sugar manufactured yearly averages about 60,629 hhds.; the quantity of molasses 3,018,041 gallons, and it is expected that this state will furnish abundance of this article for the whole consumption of the United States. The tobacco exported averages 29,543 hhds. annually, and the cotton in the same period 308,243 bales. The yearly quantity, however, depends entirely upon the season. The total amount of exports and imports in 1833 was, imports 9,590,505 dollars, and exports 18,941,373 dollars. The amount received in the state for postage for the year ending the 31st of March 1832, was 4,812,898 dollars. The number of banks in 1834 was ten, having a capital of 23,664,755 dollars, and they issued notes to the amount of 4,793,730 dollars. The number of ships belonging to the state in 1830 was 399, and the number of seamen employed 4789. (R. R. R.)

LOURDE, a city of France, in the department of the Upper Pyrenees, and arrondissement of Argelés, on the Gave de Pau. It is strongly fortified, and stands at the entrance of one of the narrowest passes into the Pyrenees. It contains 2900 houses, and 3070 inhabitants. Some flax is grown, and converted into linen cloth, which is in great repute. Long. 0. 15. W. Lat. 43. 8. N.

LOURISTAN, a mountainous district in the province of Irak, in Persia, where it borders on Khusistan. This extensive tract of country, which runs along the whole frontier of Khusistan, and extends as far to the east as the longitude of 50. and to the north as far as the latitude of 33. 40. is by far the richest and most fruitful part of Irak. From this mountainous tract several large rivers descend into the level province of Khusistan, and there is hardly a valley that is not watered by many lesser streams. The pasture is not luxuriant, and no attention is paid to agriculture; the inhabitants, the Illiats, preferring a wandering life, and principally subsisting on the produce of their flocks. They are a savage and fearless race, subject to no law but the will of their chiefs, and seem to differ only in name from the rude inhabitants of the same country in the days of Alexander. They reside in black tents, even during the winter; and consequently, with the exception of Korumabad, there are no towns, and but few villages. They deduce their descent from a high antiquity, though they do not deny that their ancestors intermarried with several Turkish hordes which they had invited from Persia to settle amongst them.

LOUTH, a maritime county in the province of Leinster, in Ireland, is bounded on the north by the county of Down and the bay of Carlingford, on the east by the Irish Sea, on the south by the county of Meath, and on the west by the counties of Meath and Monaghan. It is the smallest county of Ireland, comprising only 200,484 acres, of which 185,568 are capable of cultivation, and 14,916 are bog or unprofitable mountain.

In the time of Ptolemy it formed part of the maritime district inhabited by the Voluntii. Afterwards it was known by the name of Argiall, Orgiall, or Uriell, which also comprehended the greater part of the counties of Meath, Monaghan, and Armagh. Its leading families of Irish extraction were the O'Carrols and the M'Scanlans. It was conquered by the English under De Courcy in his progress northwards to Ulster, and formed one of the twelve counties into which King John divided that part of Ireland which acknowledged his authority. It is now divided into the five baronies of Ardee, Upper and Lower Dundalk, Ferrard, and Louth, which are subdivided into sixty-one parishes, all in the archdiocese of Armagh, and two parts of parishes in the diocese of Clogher.

The southern part of the county is flat, diversified by gentle undulations of the surface. Proceeding northwards it becomes more hilly, until, at its most northern extremity, it rises into the mountains of Ravensdale and Carlingford, of considerable elevation. The rivers are the Dee, the Clyde, the Fane, and the Castletown. None of them are navigable, being useful solely for irrigation, and other purposes of rural economy. The Boyne forms part of the southern boundary of the county. It is navigable for large vessels as far as Drogheda. The county has a considerable line of sea-coast, consisting chiefly of a sandy strand, except where it is broken by the projection of Clogher Head, a bold promontory, on which is a fishing town of the same name. The bay of Dundalk extends beyond this point for seven miles at its mouth, indenting the coast for an equal distance inland. It is considered as peculiarly dangerous for shipping. The Carlingford Mountains, which bound the northern extremity of the county, separate it from the bay that takes its name from them. This latter bay, which forms the line of demarcation both between the counties of Louth and Down and the provinces of Leinster and Ulster, is deep and narrow, extending in length upwards of nine miles, with an average breadth of a mile and a half. It is navigable nearly to the town of Newry, and its shores on both sides are much admired for their bold and picturesque scenery. An oyster, in high estimation amongst gastronomes for the peculiar delicacy of its flavour, is found in this bay.

The soil in the southern lowlands is well adapted for tillage, being composed of a rich vegetable mould resting on marl or on limestone, sometimes with a substratum of slate. The quality of the soil diminishes in agricultural value as the land rises towards the north, and the summits of the mountainous district produce only heath and scanty herbage.

The mountains are composed chiefly of granite. On their borders hornblende and primitive greenstone are found in abundance, after which are exterior ranges of transition rock. The lower lands are of the clay-slate formation. The line of separation between the granite and the clay-slate extends from Carlingford Bay, over the summit of the Ravensdale Mountains, into the county of Armagh. Flœtz limestone appears in the neighbourhood of Drogheda and Ardee. A lead mine was worked for a short period at Salterstown, near the sea-coast. There is a mineral spring at Ballymascanlan.

The returns of the population, taken at different periods, present the following results:—

1760	De Burgho	67,512
1792	Beaufort	57,750
1812	Parliamentary return	—
1821	Ditto	101,011
1831	Ditto	108,168

According to the last of these returns, the ratio of population to the total number of acres in the county is as 1 to 1·85, and to the number of acres capable of profitable cultivation as 1 to 1·69.

The county, though the smallest in Ireland, sent no fewer than twelve representatives to the Irish parliament. Two were returned for the county, two for the town of Drogheda, and two for each of the boroughs of Dundalk, Ardee, Carlingford, and Dunleer. But the act of union reduced this number to four, two for the county, one for Drogheda, and one for Dundalk; and this arrangement continues under the reform act.

The number of freeholders entitled to vote at elections of representatives for the county in parliament, at three periods, 1*st*, previously to the disqualification of the forty-shilling freeholders, 2*d*, subsequently to their disqualification, and, 3*d*, under the reform act, is as follows:—

Year.	L.50.	L.20.	L.10.	40s.	Total.
Jan. 1, 1829,	274	58	—	2343	2675
Jan. 1, 1830,	307	102	286	—	695
May 1, 1831,	295	113	380	—	788

Under the provisions of the act passed in 1836, the constabulary is to be placed under a sub-inspector, under whom there are to be five chief constables, ten head constables, and eighty constables and sub-constables. The number of the constabulary previously to this new arrangement was four chief constables and eighty sub-constables, which were maintained at an annual expense of L.3578, being at an average of L.43 nearly.

The state of education, according to the returns made to parliament in 1821 and 1824–26, is as follows:—

Year.	Boys.	Girls.	Sex not ascertained.	Total.
1821,	2740	1182	—	3922
1824–26,	4291	2584	101	6976

Of the number stated in the latter of these returns, 81 were of the Established Church, 5664 were Roman Catholics, and ninety-five Dissenters; the religious persuasion of thirty-six was not ascertained. The total number of schools was 169, of which twenty-one, affording education to 1358 children, were supported by grants of public money; twenty, affording education to 1106, were supported by the voluntary contributions of societies or individuals; and the remaining 128, in which 4512 children received instruction, were supported wholly by the fees of the pupils. There is an endowed classical school at Dundalk, on the endowment of Erasmus Smith.

The lands capable of cultivation are mostly kept in tillage. Potatoes, wheat, oats, and barley, raised according to the succession here stated, form the principal crops. In the northern districts, oats are chiefly raised. The systems generally adopted are those of the most approved kind, as are also the implements employed. From the attention paid to introduce the best breeds of cattle of every denomination, the different species cannot now be easily distinguished. Sheep are most abundant in the hilly districts. Many parts of the county are well planted; the neighbourhood of Collon particularly exhibits a fine specimen of the attention paid by its proprietor to this mode of improving and embellishing the country. The ash-tree grows in the lower grounds to a great size. The coasts furnish a constant supply of fish; and the flat shores abound with sea-fowl, especially barnacle, which, however, is not so highly esteemed for flavour as that of Wexford or Derry. The manufacture of coarse linens is carried on to a considerable extent, and latterly the cotton manufacture has gained ground.

The appearance of the dwellings of the peasantry in the smaller towns and villages indicates a considerable degree of comfort. In the hilly and more remote districts it deteriorates considerably. In their manners, food, and clothing, they differ in no respect from those of the neighbouring portions of Leinster and Ulster. Fuel is scarce, except in the vicinity of the sea-ports, into which English and Scotch coal is imported.

Few counties can boast of so many remains of antiquity. There are two round towers, one at Monasterboice, 110 feet in height, and in a state of excellent preservation; the other at Dromiskin, much decayed. At the former of these places there are also the remains of two chapels, and of two finely-sculptured crosses, one of them eighteen feet high. Near the banks of a stream called the river of Balrichan, is a large artificial cave, accidentally discovered by the sinking in of a horse whilst ploughing. It consists of several narrow passages, the sides and top of which are formed of flag-stones. Some bones of large and small animals were found in it. About two miles from Dundalk are the ruins of a very ancient structure, which has some resemblance to the hull of an ancient galley. There are no traces of doors, windows, or loop-holes. The building has given rise to much antiquarian discussion. At Ballymascanlan is a cromleach called the Giant's Load. It consists of a rock twelve feet long and six broad, elevated on three upright stones. Near it is Castle Rath, surrounded by moats and lesser raths, and with a remarkable tumulus in its vicinity. The great mound of Castleguard, near Ardee, is ninety feet in height, and 600 feet in circumference at its base. Its summit terminates in an area 140 feet round. It is well planted, and surrounded by a deep trench. At Faughart are the remains of an ancient intrenchment. The decisive battle which terminated in the defeat and death of Edward Bruce, by Sir John Bermingham, afterwards Lord Louth, was fought near this place. The remains of castles are numerous. That of Carlingford, built by King John, occupies a commanding position on a rock projecting into the bay. Castletown stands within sight of the town of Dundalk. Terfeckan Castle, once the residence of the learned Archbishop Usher, is now utterly in ruins. The county is equally remarkable for the number of its ancient monastic edifices. Mellifont, a Cistertian abbey, five miles west of Drogheda, presents some remains equally remarkable for their beauty and singularity of architecture. Others are to be traced at Carlingford, Faughart, and Monasterboice.

The principal modern seats are, Collon, the residence of Lord Oriell; Barmeath, belonging to the Bellew family; Rokeby Hall, the mansion of the Count de Salis; Louth Hall, that of Lord Louth; Ravensdale Park; and Clermont.

Dundalk, the county-town, a place of great antiquity, is situated at the mouth of the Castletown River. It consists of one long street, intersected by some cross passages. Its most remarkable building is the court-house, the front of which, modelled from the temple of Theseus at Athens, is considered as the finest specimen of pure Grecian architecture in Ireland. The other public buildings are, the parish church, two Roman Catholic chapels, a large barrack, a gaol, assembly and news rooms, a linen-hall, a charter school, and an infirmary. Dundalk is a great mart for the export of grain. The harbour is commodious but shallow. The cambric manufacture is carried on to some extent. Its population, in 1831, amounted to 10,078 souls. The other towns containing a population of upwards of one thousand souls are, Ardee 3975, Carlingford 1319, Collon 1153.

Louth, a market-town of the county of Lincoln, in the hundred of Louth Eske, in Lindsay division. It is 144 miles from London, being situated on the river Lud, from which a canal has been constructed, communicating with the sea, about seven miles distant. It has a considerable coasting trade, and good markets on Wednesdays and Saturdays. It is governed by a corporate body, composed of a warden and six assistants. The population amounted in 1801 to 4236, in 1811 to 4728, in 1821 to 6012, and in 1831 to 6927.

LOUVAIN, or Loewen, a circle of the province of South Brabant, in the Netherlands. It comprehends eight cantons, divided into 144 communes, containing 133,840 inhabitants. The capital is the city of the same name, situated on the river Dyle. It has water communication by the Louvain Canal with Mechlin, and by the river Rupel with the Scheldt. Its walls are extensive, but three fourths of the land they encompass consist of fields and gardens. It contains 4000 houses, and 25,000 inhabitants, who carry on extensive breweries and distilleries, spin cotton twist, print calicoes, and grind much corn into flour. It is the seat of an ancient university, and has a stadthouse of Gothic architecture, constructed by Charlemagne. Long. 4. 36. E. Lat. 50. 33. N.

LOUVIERS, an arrondissement of the department of the Eure, in France, extending over 410 square miles, and inhabited by 65,800 persons. It is divided into five cantons and 122 communes. The capital is the city of the same name, situated on the river Eure. It stands on an island formed by two arms of that river, and is surrounded with walls and ditches. It contains 1050 houses, with 7500 inhabitants, who make some of the finest cloths and casimeres in France, and manufacture several kinds of cotton goods. Long. 1. 5. E. Lat. 49. 10. N.

LOVE, in the enlarged sense of the word, denotes all those affections of the pleasing kind which objects and incidents excite in our minds. Thus we are said to *love* not only intelligent agents of morally good dispositions, but also sensual pleasures, riches, and honours.

But *love*, in its usual and more appropriate signification, may be defined, "that affection which, being compounded of animal desire, esteem, and benevolence, becomes the bond of attachment and union between individuals of the different sexes, and makes them enjoy in the society of each other a species of happiness which they experience nowhere else." We call it an *affection* rather than a *passion*, because it involves a desire of the happiness of its object; and that its constituent parts are such as have just been enumerated we shall first endeavour to prove, and then proceed to trace its rise and progress from a selfish appetite to a generous sentiment.

Mere animal desire has nothing in view but the species and the sex of its object; and before it makes a selection, it must be combined with sentiments very different from itself. The first sentiment with which it is combined, and by which a man is induced to prefer one woman to another, seems to be that by which we are delighted with gracefulness of person, regularity of features, and beauty of complexion. It is not indeed to be denied that there is something irresistible in female beauty. The most severe will not pretend that they do not feel an immediate prepossession in favour of a handsome woman; but this prepossession, even when combined with animal desire, does not constitute the whole of that affection which is called *love*. Savages feel the influence of the sensual appetite, and it is extremely probable that they have some ideas of beauty; but amongst savages the affection of love is seldom known. Even amongst the lower orders of society it seems to be a very gross passion, and to have in it more of the selfishness of appetite than of the generosity of esteem. To these observations many exceptions will no doubt be found;[1] but we speak of savages in general, and of the great body of the labouring poor, who, in the choice of their mates, do not study, and indeed are incapable of studying, that rectitude of mind, and those delicacies of sentiment, without which neither man nor woman can deserve to be esteemed.

In the savage state, and even in the first stages of refinement, the bond of union between the sexes seems to consist of nothing more than mere animal desire and instinctive tenderness for their infant progeny. The former impels them to unite for the propagation of the species, and the latter preserves the union until the children who are the fruit of it be able to provide for their own subsistence. That in such unions, whether casual or permanent, there is little mutual esteem and benevolence, is apparent from the state of subjection in which women are held in rude and uncultivated nations, as well as from the manner in which marriages are contracted.

Sweetness of temper, a capital article with us in the female character, displays itself externally in mild looks and gentle manners, and is the first and perhaps the most powerful inducement to love in a cultivated mind. "But such graces," says Lord Kames, "are scarce discernible in a female savage, and even in the most polished woman would not be perceived by a male savage. Among savages, strength and boldness are the only valuable qualities. In these, females are miserably deficient; for which reason they are contemned by the males, as beings of an inferior order. The North American tribes glory in idleness; the drudgery of labour degrades a man in their opinion, and is proper for women only. To join young persons in marriage is accordingly the business of the parents; and it would be unpardonable meanness in the bridegroom to show any fondness for the bride. In Guiana a woman never eats with her husband, but after every meal attends him with water for washing; and in the Caribbee islands she is not even permitted to eat in the presence of her husband. Dampier observes in general, that among all the wild nations with which he was acquainted, the women carry the burdens, while the men walk before and carry nothing but their arms; and that women even of the highest rank are not better treated. In Siberia, and even in Russia, the capital excepted, men, till very lately, treated their wives in every respect like slaves. It might indeed be thought that animal desire, were there nothing else, should have raised women to some degree of estimation among men; but male savages, utter strangers to decency and refinement, gratify animal desire with as little ceremony as they do hunger or thirst. Hence it was that in the early ages of society a man purchased a woman to be his wife, as one purchases an ox or a sheep to be food; and valued her only as she contributed to his sensual gratification."

---

[1] Such as that of the negroes whose story is so pathetically told by Addison (*Spectator*, No. 215); the two lovers who were killed by lightning at Staunton-Harcourt (Pope's *Letters*); and many others which will readily occur to every reader.

But if amongst savages and the vulgar, love be unknown, it cannot possibly be an instinctive affection; and therefore it may be asked how it gets possession of the human heart, and by what means we can judge whether in any particular instance it be real or imaginary. These questions are of importance, and deserve to be fully answered, though many circumstances conspire to render it no easy task to give to them such answers as may be perfectly satisfactory. Love can subsist only between individuals of the different sexes. A man can hardly love two women at the same time; and we believe that a woman is still less capable of loving at once more than one man. Love, therefore, has a natural tendency to make men and women pair, or, in other words, it is the source of marriage; but in polished society, where alone this affection has any place, so many things besides mutual attachment are necessary to make the married life comfortable, that we rarey see young persons uniting from the impulse of love, and have therefore but few opportunities of tracing the rise, progress, and consequences of the affection. We shall, however, throw together such reflections as have occurred to us on the subject, not without indulging a hope that they may be useful to the younger part of our readers when forming the most important connexion in life.

We have said that the perception of beauty, combined with animal desire, is the first inducement which a man can have to prefer one woman to another. It may be added, that elegance of figure, a placid masculine countenance, with a person which indicates strength and agility, are the qualities which first tend to attach any woman to a particular man. Beauty has been defined by Buffier, "that particular form which is the most common of all particular forms to be met with in the same species of beings." Let us apply this definition to our own species, and try, by means of it, to ascertain what constitutes the beauty of the human face. It is evident, that of countenances we find a number almost infinite of different forms; of which, however, one only constitutes beauty, whilst the rest, however numerous, constitute what is not beauty, but deformity or ugliness. To an attentive observer, however, it is evident, that of the numerous particular forms of ugliness, there is not one which includes so many faces as are formed after that particular cast which constitutes beauty. Every particular species of the animal as well as the vegetable creation may be said to have a fixed or determinate form, to which, as to a centre, nature is continually inclining. Or it may be compared to pendulums vibrating in different directions over one central point; and as they all cross the centre, though only one passes through any other point, so it will be found that perfect beauty is oftener produced by nature than deformity; we do not mean than deformity in general, but than any one kind and degree of deformity. To instance in a particular part of a human feature; the line which forms the ridge of the nose is deemed beautiful when it is straight; but this is likewise the central form, which is oftener found than any one particular degree of concave, convex, or any other irregular form that may be proposed. As we are then more accustomed to beauty than deformity, we may conclude that that is the reason why we approve and admire it, just as we approve and admire fashions or dress for no other reason than that we are used to them. The same thing may be said of colour as of form. It is custom alone which determines our preference of the colour of the Europeans to that of the Ethiopians, and which makes them prefer their own colour to ours; so that though habit and custom cannot be the cause of beauty, they are certainly the cause of our liking it.

That we do like it cannot be denied. Every one is conscious of a pleasing emotion when contemplating beauty either in man or woman; and when that pleasure is combined with the gratification of the sensual appetite, it is obvious that the sum of enjoyment must be greatly increased. The perception of beauty, therefore, necessarily directs the energy of the sensual appetite to a particular object; but still this combination is a mere selfish feeling, which regards its object only as the best of many similar instruments of pleasure. Before it can deserve the name of love, it must be combined with esteem, which is never bestowed but upon moral character and internal worth; for let a woman be ever so beautiful, and of course ever so desirable as an instrument of sensual gratification, if she be not possessed of the virtues and dispositions which are peculiar to her sex, she will inspire no man with a generous affection. With regard to the outlines, indeed, whether of internal disposition or of external form, men and women are the same; but nature, intending them for mates, has given them dispositions which, though concordant, are however different, so as to produce together delicious harmony. "The man, more robust, is fitted for severe labour, and for field exercise; the woman, more delicate, is fitted for sedentary occupations, and particularly for nursing children. The man, bold and vigorous, is qualified for being a protector; the woman, delicate and timid, requires protection. Hence it is that a man never admires a woman for possessing bodily strength or personal courage; and women always despise men who are totally destitute of these qualities. The man, as a protector, is directed by nature to govern; the woman, conscious of inferiority, is disposed to obey. Their intellectual powers correspond to the destination of nature. Men have penetration and solid judgment to fit them for governing, women have sufficient understanding to make a decent figure under a good government; a greater portion would excite dangerous rivalship between the sexes, which nature has avoided by giving them different talents. Women have more imagination and sensibility than men, which make all their enjoyments more exquisite; at the same time that they are better qualified to communicate enjoyment. Add another capital difference of disposition: The gentle and insinuating manners of the female sex tend to soften the roughness of the other sex; and wherever women are indulged with any freedom, they polish sooner than men.

"These are not the only particulars that distinguish the sexes. With respect to the ultimate end of love, it is the privilege of the male, as superior and protector, to make a choice; the female preferred has no privilege but barely to consent or to refuse. Whether this distinction be the immediate result of the originally different dispositions of the sexes, or only the effect of associations inevitably formed, may be questioned; but among all nations it is the practice for men to court, and for women to be courted; and were the most beautiful woman on earth to invert this practice, she would forfeit the esteem, however by her external grace she might excite the desire, of the man whom she addressed. The great moral virtues which may be comprehended under the general term integrity, are all absolutely necessary to make either men or women estimable; but to procure esteem to the female character, the modesty peculiar to their sex is a very essential circumstance. Nature hath provided them with it as a defence against the artful solicitations of the other sex before marriage, and also as a support of conjugal fidelity."

A woman, therefore, whose dispositions are gentle, delicate, and rather timid than bold, who is possessed of a large share of sensibility and modesty, and whose manners are soft and insinuating, must, upon moral principles, command the esteem and benevolence of every individual of the other sex who is possessed of sound understanding; but if her person be deformed, or not such as to excite some degree of animal desire, she will attract no man's love. In like manner, a man whose moral character is good, whose understanding is acute, and whose conversation is instructive, must command the esteem of every sensible and virtuous woman; but if his figure be disagreeable, his manner unpolished, his habits slovenly, and, above all, if he be deficient in personal courage, he will hardly excite desire in the female breast. It is only when the qualities which command esteem are, in the same person, united with those which excite desire, that the individual so accomplished can be an object of love to one of the other sex; but when these qualities are thus united, each of them increases the other in the imagination of the lover. The beauty of his mistress gives her, in his apprehension, a greater share of gentleness, modesty, and every thing which adorns the female character, than perhaps she really possesses; whilst his persuasion of her internal worth makes him, on the other hand, apprehend her beauty to be absolutely unrivalled.

To this theory an objection readily offers itself, which it is incumbent upon us to obviate. Men and women sometimes fall in love at first sight, and very often before they have opportunities of forming a just estimate of each other's moral character. How is this circumstance to be reconciled with the progressive generation of love? We answer, by an association of ideas, which is formed upon principles of physiognomy. Every passion and habitual disposition of mind gives a particular cast to the countenance, and is apt to discover itself in some feature of the face. This we learn by experience; and in time, without any effort of our own, the idea of each particular cast of countenance comes to be so closely associated in our minds with the internal disposition which it indicates, that the one can never afterwards be presented to our view without instantly suggesting the other to the imagination. Hence it is that every man, who has been accustomed to make observations, naturally forms to himself, from the features and lineaments of a stranger's face, some opinion of his character and fortune. We are no sooner presented to a person for the first time, than we are immediately impressed with the idea of a proud, a reserved, an affable, or a good-natured man; and upon our going into a company of absolute strangers, our benevolence or aversion, our awe or contempt, rises instantly towards particular persons, before we have heard them speak a word, or know so much as their names or designations. The same thing happens when we are presented to the fair sex. If a woman, seen for the first time, have that particular cast of countenance, and that expression of features, with which we have associated notions of gentleness, modesty, and other female virtues, she instantly commands our esteem; and if she have likewise so much beauty as to make her an object of particular desire, esteem and desire become suddenly combined, and that combination constitutes the affection of love. Such, too, is the nature of all mental associations, that each part of which they are composed adds strength and vividness to the other parts; so that, in the present instance, desire makes us imagine virtues in the woman which her countenance perhaps does not indicate, and the virtues which are there actually visible make us apprehend her beauty as more perfect than it is.

LOVE, in *Medicine.* The symptoms produced by this passion as a disease, according to medical writers, are various. The eyelids often twinkle; the eyes are hollow, and yet appear as if full with pleasure; the pulse is not peculiar to the passion, but the same with that which attends solicitude and care. When the object of this affection is thought of, particularly if the idea be sudden, the spirits are confused, the pulse changes, and its force and time are very variable. In some instances, the person is sad and watchful; in others, the person, not being conscious of his state, pines away, is slothful, and regardless of food; though the wiser, when they find themselves in love, seek pleasant company and active entertainments. As the force of love prevails, sighs grow deeper; a tremor affects the heart and pulse; the countenance is alternately pale and red; the voice is suppressed in the fauces; the eyes grow dim; cold sweats break out; sleep absents itself, at least until the morning; the secretions become disturbed; and a loss of appetite, a hectic fever, melancholy, or perhaps madness, if not death, constitutes the catastrophe. (On this subject the curious may consult Ægineta, lib. iii. 17; Oribat. *Synon.* lib. viii. cap. 9; or a treatise on Love as a distemper, by John Ferrard, Oxford, 1640.)

The manners of the Greeks and Romans were similar to each other in the affairs of love. They generally made a discovery of their passion by writing upon trees, walls, doors, and other places, the name of their beloved. They usually decked the door of their dulcinea with flowers and garlands, and made libations of wine before their houses, sprinkling the posts with the same liquor, as if the object of their affection was a real goddess. For a man's garland to be untied, and for a woman to compose a garland, were held to be indubitable indications of love.

When their love was without success, they used several arts to excite affection in the object of their desire. They had recourse to enchantresses, of whom the Thessalian were in the highest estimation. The means made use of were most commonly philtres or love potions, the operation of which was violent and dangerous, and frequently deprived such as drank them of their reason. Some of the most remarkable ingredients of which they were composed were the hippomanes, the jynx, insects bred from putrefaction, the fish remora, the lizard, the brains of a calf, the hairs on the tip of a wolf's tail, his secret parts, the bones of the left side of a toad eaten with ants, the blood of doves, the bones of snakes, feathers of screech-owls, twisted cords of wool in which a person had hanged himself, rags, torches, reliques, a nest of swallows buried and famished in the earth, bones snatched from hungry bitches, the marrow of a boy famished in the midst of plenty, dried human liver; to which may be added several herbs growing out of putrid substances. Such were the ingredients that entered into the composition of that infernal draught called a love potion.

But, besides the philtres, various other arts were used to excite love; in which the application of certain substances was to have a magical influence on the person against whom they levelled their skill. A hyena's udder worn under the left arm, they fancied would draw the affections of whatever woman they fixed their eyes upon. That species of olives called *μιτυρα*, and barley-bran made into a paste, and thrown into the fire, they thought would excite the passion of love. Flour was used with the same intention; and burning laurel, and melted wax, were supposed to have a similar effect. When one heart was to be hardened and another mollified, clay and wax were exposed to the fire together. Images of wax were frequently used, representing the persons on whom they wished to make an impression; and whatever was done to the substitute of wax, they imagined was felt by the person represented. Enchanted medicaments were often sprinkled upon some part of the house where the person resided. Love-pledges were supposed to be of singular use and efficacy; these they placed under the threshold, to preserve the affections of the owner from wandering. Love-knots were also of singular power, and the number three was particularly observed in all they did. But no good effect was expected if the use of these things had not been attended with charms or magical verses and forms of words.

Having mentioned their arts of exciting love, it may not be amiss to take notice that the ancients imagined that love excited by magic might be allayed by more powerful spells and medicaments, or by application to demons more powerful than those who had been concerned in raising that passion. But love inspired without magic had no cure; Apollo himself could find no remedy, but exclaimed, "Hei mihi quod nullis amor est medicabilis herbis." The antidotes against love were generally, *agnus castus*, which has the power of weakening the generative faculty; sprinkling the dust in which a mule had rolled herself; tying toads in the hide of a beast newly slain; applying amulets of minerals or herbs, which were supposed of great efficacy in other cases; and invoking the assistance of the inferior deities. Another cure for love was bathing in the waters of the river Selemnus; to which we may add, the lover's leap, or jumping down from the Leucadian promontory.

LOVERE, a city of Italy, in the delegation Bergamo, and the Austrian government of Milan. It is situated on the lake Iseo, in the beautiful vale of Cavallino, and has a church and several religious houses, with 4010 inhabitants, who carry on some woollen manufactories.

LOWANCE, a considerable river of Persia, in the province of Mekran. It runs through a fertile valley, on the banks of which there is a considerable number of inhabitants, who live in tents, and are industrious cultivators. Lowance is fifty miles west of Bayla.

LOWASHAN, a province of the Burman empire, situated between the twenty-second and twenty-fourth degrees of north latitude. On the north and east it is bounded by the province of Yunan in China, on the south by the country of Yunshan, and on the west by Ava proper. The country is watered by the Lookiang or Thalnayn river. It is mountainous, and but little known.

LOW-BELL, in birding, a name given to a bell by means of which birds are taken in the night, in open champaign countries, and amongst stubble. The method is to go out about nine o'clock at night in a still evening, when the air is mild and the moon does not shine. The low-bell should be of a deep and hollow sound, and of such a size that a man may conveniently carry it in one hand. The person who carries it makes it toll all the way he goes, as nearly as may be, in the same manner in which the bell on the neck of a sheep tolls as it goes on and feeds. There must also be a box made like a large lanthorn, about a foot square, and lined with tin, but with one side open. Two or three great lights are to be set in this; and the box is to be fixed to the person's breast, with the open side forwards, so that the light may be cast forward to a great distance. It will spread as it goes out of the box, and distinctly show to the person that carries it whatever there is in the large space of ground over which it extends, and consequently all the birds that roost upon the ground. Two persons must follow him who carries the box and bell, one on each side, so as not to be within the reach of the light to show themselves. Each of these is to have a hand-net, of about three or four feet square, fastened to a long stick or pole; and on whichever side any bird is seen at roost, the person who is nearest is to lay his net over it, and take it with as little noise as possible. When the net is over the bird, the person who laid it is not to be in a hurry to take the bird, but must stay till he who carries the light is got beyond it, that his motions may not be discovered. The blaze of the light and the noise of the bell terrify and amaze the birds in such a manner that they remain still to be taken; but the people who are engaged in the work must keep as quiet and still as may be. Some people are fond of going on this sport alone. The person then fixes the light box to his breast, and carries the bell in one hand and the net in the other; the net in this case may be somewhat smaller, and the handle shorter. When more than one are out at a time, it is always proper to carry a gun, as it is no uncommon thing to spy a hare when on this expedition.

LOWER, RICHARD, an eminent English physician in the seventeenth century, was born in Cornwall, and educated at Westminster school and Oxford. He afterwards studied medicine, and practised under Dr Thomas Willis, whom he instructed in some parts of anatomy, especially when the latter was writing his *Cerebri Anatome.* In 1674, Lower, along with Dr Willis, discovered the medicinal waters at Ashop, in Northamptonshire, which, upon their recommendation, became very much frequented. In 1666, he followed Dr Willis to London, practised physic under him, and became a fellow of the Royal Society, and also of the College of Physicians. In 1669 he published his *Tractatus de Corde;* and after the death of Dr Willis in 1675, he was esteemed the most eminent physician in London. Upon the breaking out of the Popish Plot in 1678, he closed with the Whigs, supposing that that party would carry all before them; but being mistaken, he lost his credit and practice together. Lower died in 1691.

LOWERING, amongst distillers, a term employed to express the debasing the strength of any spirituous liquor, by mixing water with it. The standard and marketable price of these liquors is fixed in regard to a certain strength in them called *proof;* or that strength which makes them, when shaken in a phial or poured from on high into a glass, retain for some time a froth or crown of bubbles. In this state spirits consist of about half pure or totally inflammable spirit, and half water; and if any foreign or home spirit be exposed to sale, and found to have that proof wanting, scarcely any body will buy it until it has been distilled again and brought to the proper strength; and if it be above that strength, the proprietor usually adds water to bring it down to the standard. There is another kind of lowering amongst the retailers of spirituous liquors to the vulgar, by reducing it under the standard proof. Whoever has the art of doing this without destroying the bubble proof, which is easily done by means of some addition which gives a greater tenacity to the parts of the spirits, will deceive all who judge by this proof alone. In this case the best way to judge of liquors is by the eye and the tongue, and especially by the instrument called the hydrometer.

LOWESTOFF, a town of the county of Suffolk, in the hundred of Mutford with Lothingland, 114 miles from London. It stretches along a cliff two furlongs from the sea-shore. It has a considerable share of the herring, as well as of the mackerel fishery, and is much frequented for sea-bathing in the summer. A canal uniting Norwich with the sea at this place has been recently finished, and promises to add to its prosperity. The church is a fine Gothic building. The market is held on Wednesday. The population amounted in 1801 to 2332, in 1811 to 3189, in 1821 to 3675, and in 1831 to 4394.

LOWTH, DR WILLIAM, a learned and pious divine, born at London in 1661, was the son of an apothecary, and took his degrees at Oxford. His eminent worth and learning recommended him to Dr Mew, bishop of Winchester, Lowth.

who made him his chaplain, gave him two livings in Hampshire, and conferred upon him a prebend in the cathedral of Winchester. Although he had acquired an unusual share of critical learning, the labours of Mr Lowth were strictly confined within the limits of his own province, and he applied solely to the peculiar duties of his function; yet, in order that he might acquit himself the better in theology, he pursued his studies with a more general and extensive view. Few were more deeply versed in critical learning, there being scarcely any ancient author, Greek or Latin, profane or ecclesiastical, which he had not read with accuracy, constantly accompanying his reading with critical and philological remarks. Of his collections in this way he was upon all occasions very communicative. Hence his notes on Clemens Alexandrinus, which are to be met with in Potter's edition of that father; and his remarks on Josephus, communicated to Hudson for his edition, and acknowledged in the preface; as also those larger and more numerous annotations upon the Ecclesiastical Historians, inserted in Reading's edition of them at Cambridge. The author of the *Bibliotheca Biblica* was indebted to him for the same kind of assistance. Chandler, bishop of Durham, whilst engaged in his Defence of Christianity, from the Prophecies of the Old Testament, against the Discourse of the Grounds and Reasons of the Christian Religion, and in his Vindication of the Defence, in answer to the Scheme of Literal Prophecy considered, held a constant correspondence with Lowth, and consulted him upon many difficulties which occurred in the course of that work. But the most valuable part of his character was that which least appeared in the eyes of the world; the private and retired part, that of the good Christian and the useful parish priest. His piety, his diligence, his hospitality and beneficence, rendered his life highly exemplary, and greatly enforced his public exhortations. He married Margaret, daughter of Mr Robert Pitt, of Blandford, by whom he had two sons and three daughters; and died in 1732, when, by his own orders, he was buried in the churchyard of Buriton. He published, 1. A Vindication of the Divine Authority and Inspiration of the Old and New Testaments; 2. Directions for the profitable reading of the Holy Scriptures; 3. Commentaries on the Prophets; and some other works.

Lowth, *Dr Robert*, second son of the preceding Dr William Lowth, and successively bishop of St David's, Oxford, and London, was born on the 29th of November 1710, probably at Buriton, in the county of Hants. He received the rudiments of his education at Winchester College, where his school exercises were distinguished by uncommon elegance; and having resided the requisite number of years in that seminary, he in 1730 succeeded to a place on the foundation at New College, Oxford. He took the degree of master of arts on the 8th of June 1737. Though his abilities must have been known to those with whom he was connected, he was not forward to appear before the world as a writer. At Oxford he continued many years improving his talents, with little notice from the great, and with so small preferment that, at this time, he escaped the distinct recollection of some of his contemporaries.

He was not, however, suffered to languish for ever in obscurity. His genius and his learning forced themselves upon the notice of the illustrious society of which he was a member; and he was placed in a station where he was eminently qualified to shine. In 1741 he was elected by the university to the professorship of poetry, re-elected in 1743, and, whilst he held that office, he read his admirable lectures *De Sacra Poesi Hebræorum*. In 1744 Bishop Hoadly collated him to the rectory of Ovington in the county of Hants; added to it, nine years afterwards, the rectory of East Weedhay in the same county; and in the interim raised him to the dignity of archdeacon of Winchester. These repeated favours he some years afterwards acknowledged in the following manly and respectful terms of gratitude: "This address, my lord, is not more necessary on account of the subject, than it is in respect of the author. Your lordship, unsolicited and unasked, called him from one of those colleges to a station of the first dignity in your diocese, and took the earliest opportunity of accumulating your favour upon him, and of adding to that dignity a suitable support. These obligations he is now the more ready thus publicly to acknowledge, as he is removed out of the reach of further favours of the like kind. And though he hath relinquished the advantages so generously conferred on him, yet he shall always esteem himself highly honoured in having once enjoyed the patronage of the great advocate of civil and religious liberty."

On the 8th of July 1754 the university of Oxford conferred upon him the degree of doctor of divinity by diploma; an honour which, as it is never granted but to distinguished merit, was probably conferred on Mr Lowth in consequence of his prelections on Hebrew poetry, which had then been recently published. Having in 1749 travelled with Lord George and Lord Frederick Cavendish, he had a claim upon the patronage of their family; and in 1755 the Duke of Devonshire being then lord lieutenant of Ireland, Dr Lowth went to that kingdom as his grace's first chaplain. Soon after this appointment he was offered the bishopric of Limerick; but having preferred a less dignified station in his own country, he exchanged it with Dr Leslie, prebendary of Durham and rector of Sedgefield, for these preferments. In November 1765 he was chosen a fellow of the Royal Society. In June 1766 he was, on the death of Dr Squire, preferred to the bishopric of St David's, which, in the October following, he resigned for that of Oxford, vacant by the translation of Bishop Hume to Salisbury. In April 1777 he was translated to the see of London, vacant by the death of Bishop Terrick; and in 1783 he declined the offer of the primacy of all England.

Having been grievously afflicted with the stone, and having long borne the severest sufferings of pain and sickness with the most exemplary fortitude and resignation, this great and good man died at Fulham on the 3d of November 1787; and on the 12th his remains were privately interred in a vault at Fulham church, near to those of his predecessor. He had married in 1752, Mary, the daughter of Laurence Jackson of Christ Church, Hampshire, by whom he had two sons and five daughters. His lady and two children only survived him.

His literary character may be estimated from the value and the importance of his works, in the account of which we may begin with his *Prelections on Hebrew Poetry.* The choice of so interesting a subject naturally attracted general attention; and the work has been read with equal applause abroad and at home. In these Prelections the author has acquitted himself in the most masterly manner, as a poet, a critic, and a divine; and such is the classical purity of his Latin style, that though we have read the work with the closest attention, and with no other view than to discover, if possible, Anglicisms in the composition, we found not a single phrase to which, we believe, a critic of the Augustan age would have objected. This is an excellence to which neither Milton nor Johnson has attained, to which indeed no other English writer of Latin with whom we are acquainted has attained, unless, perhaps, Bishop Atterbury be excepted. To the Prelections was subjoined a short confutation of Bishop Hare's system of Hebrew metre, which occasioned a Latin letter from Dr Edwards of Clare Hall, Cambridge, to Dr Lowth, in vindication of the Hare metre. To this the author of the Prelections replied in a larger confutation, in which Bishop Hare's system is completely overthrown, and the fallacy upon which it was built accurately investigated and exposed. After much attentive consideration, Bishop Lowth has pronounced the metre of the Hebrews to be perfectly irrecoverable.

In 1758 he published *The Life of William of Wykeham*, bishop of Winchester, with a dedication to Bishop Hoadly, which involved him in a dispute concerning a decision which that bishop had lately pronounced respecting the wardenship of Winchester College. This controversy was on both sides carried on with such ability, that, though relating to a private concern, it may yet be read, if not with pleasure, at least with improvement. The life of Wykeham is drawn from the most authentic sources, and affords much information concerning the manners, and some of the public transactions, of the period in which Wykeham lived, whilst it displays some private intelligence respecting the two literary societies of which he was the founder. In these societies Dr Lowth was educated, and he gratefully expresses his obligations to them.

In 1762 was first published his *Short Introduction to English Grammar*, which has since gone through so many editions. It was originally designed only for private and domestic use; but its judicious remarks being too valuable to be confined to a few, the book was given to the world; and the excellence of its method, which teaches what is right by showing what is wrong, has insured public approbation and very general use. In 1765 Dr Lowth was engaged with Bishop Warburton in a controversy, which made much noise at the time, and attracted the notice even of royalty itself. If we do not wish to dwell upon the particulars of this controversy, it is because violent literary contention is an evil which, though, like other war, it may sometimes be unavoidable, yet is always to be regretted; and because the characters of learned, ingenious, and amiable men never appear to less advantage than under the form which that state of literary hostility obliges them to assume.

In 1778 Bishop Lowth published his last great work, *A Translation of Isaiah*. To his literary and theological abilities the translator joined the most critical knowledge of the character and spirit of eastern poetry; and accordingly the prophecies of Isaiah, which, though almost always sublime or elegant, are yet sometimes obscure, were translated in a manner adequate to the highest expectations of the public. Several occasional discourses which the bishop, by his station, was at different times called upon to deliver, were of course published, and are all worthy of their excellent author; but there is one on the kingdom of God, on the extension and progressive improvement of Christ's religion, and on the means of promoting these by the advancement of religious knowledge, by freedom of inquiry, by toleration, and mutual charity, which may be distinguished from the rest, as exhibiting a most comprehensive view of the successive states of the Christian church, and containing the truest principles of Christianity.

Of the bishop's poetical pieces, none display greater merit than verses on the Genealogy of Christ, and the Choice of Hercules, both composed very early in life. He wrote a spirited Imitation of an Ode of Horace, applied to the alarming situation of this country in 1745; and likewise some verses upon the death of Frederick, prince of Wales, with a few smaller poems.

Learning and taste, however, did not constitute Bishop Lowth's highest excellence. Eulogium itself can scarcely ascend to extravagance when speaking of him either as a private man, or as a pastor of the church of Christ. His amiable manners rendered him an ornament to his high station, whilst they endeared him to all with whom he conversed; and his zeal for the interests of true religion made him eager to advance to places of trust and dignity such clergymen as he knew were best qualified to fill them.

LOXA, a province of Colombia, in the department of Azuay, bounded on the north by Guayaquil, on the east by Jaen, on the south by Yaguarsongo, and on the west by Zamora. It is situated on an elevated and healthy situation, fertile in all kinds of grain. It affords the finest cinchona, and was long supposed to be the only place which produced that medicament in any degree of perfection. Cochineal is also found in considerable abundance. Its principal commerce consists in woven stuffs of cotton, wool, and carpet, which are held in high estimation. It possesses also two or three gold mines, which are worked. Its chief town is Loxa, situated in a beautiful and extensive valley, between two streams, which flow from the Andes. It was formerly a place of considerable importance, though now much decayed, and still contains several convents. Long. 79. 15. W. Lat. 3. 59. S.

LOYOLA, Ignatius. See Ignatius.

LOZENGE, in *Heraldry*, a four-cornered figure, resembling a pane of glass in old casements. Though all heralds agree that single ladies are to place their arms on lozenges, yet they differ with respect to the causes which gave rise to it. Plutarch says, in the life of Theseus, that in Megara, an ancient town of Greece, the tombstones under which the bodies of the Amazons lay were shaped after that form, which some conjecture to be the cause why ladies have their arms on lozenges. Petra Sancta conceives this shield to represent a *cushion*, whereupon women used to sit and spin, or do other housewifery; but Ferne thinks that it is formed from the shield called *tessera*, which the Romans, finding unfit for war, allowed to women to place their ensigns upon, with one of its angles always uppermost.

Lozenges, amongst jewellers, are common to brilliant and rose diamonds. In brilliants, they are formed by the meeting of the skill and star facets on the bezil; in the latter, by the meeting of the facets in the horizontal ribs of the crown.

Lozenge is also a form of medicine, made into small pieces, to be held or chewed in the mouth till they are melted there, and are the same with what are otherwise called *trochisci*, troches.

LOZERE, a department of the south-west of France, formed out of the district of Sevaudan, a part of ancient Languedoc. It extends in north latitude from 44. 2. to 44. 59., and in east longitude from 2. 51. to 3. 50., containing 2134 square miles, or 509,543 hectares. It is bounded on the north by the departments of the Upper Loire and Cantal, on the east by the Ardèche, on the south by the Gard, and on the west by Aveyron. It comprehends twenty-four cantons, divided into 193 communes, and contains a population of 148,000 persons, of whom the Protestants, chiefly in the arrondissement of Florac, are between thirty and forty thousand. It is a lofty, cold, raw, and hard mountain district, the most sterile and the most thinly peopled of any part of France. In the fields are to be seen rocks of granite, or of chalk, scattered about as high as the houses, whilst in the south the whole seems to be slate covered with chalk. No river runs into the department, but several streams issue from it in different directions, and form rivers, such as the Lozère, the Lot, the Allier, and the Ardèche. The climate is raw and cold, but not unhealthy. Agriculture is ill conducted, and this, with the natural poverty of the soil, causes a necessity for the importation of annual quantities of corn. No other but rye and oats, with some little barley, is raised; and chestnuts, with potatoes, form substitutes for corn with the great mass of the people, who are as ill clad as they are poorly fed. In the summer the workmen wander into the more southern departments, and even into Spain, to gain a little by their work in time of harvest. The chief branch of industry was spinning, which all practised during their long winter; but that employment has diminished by the extension of machinery. Some serges, and other coarse woollens, are, however, still manufactured. Fuel is very scarce, the woods having been ruined by neglect; and no coal is extracted. The only mineral obtained is lead, but the quantity does not exceed forty tons; and this, with some wool, hides, and cattle, forms the chief trade. The department sends one deputy to the legislative chamber. The capital is the city of Mende.

LOZOLO, a town of the province of Vercelli, in Piedmont, surrounded with several smaller places, the population of which amounts to 6450 persons, who cultivate extensively rice, and breed silk-worms.

LUBEC, an island in the Eastern Seas, which is populous, and carries on a considerable trade with Borneo and Java, off the northern coast of which it is situated. It is surrounded by a cluster of rocks and rocky islets. Long. 112. 45. E. Lat. 3. 48. S.

LUBECK, an independent republic in the north of Germany, consisting of the city of that name, a part of the town of Bergedorf, divided between Hamburg and Lubeck, and sixty-eight villages and hamlets. It extends over 148 square miles, and contains 6437 houses, and 46,508 inhabitants, who all profess the Lutheran religion, except 300 Calvinists, 400 Catholics, and 300 Jews. The income of the state amounts to L.40,000 a year, but is burdened with a heavy debt of near L.300,000. It is governed by a senate of four burgomasters and sixteen counsellors, with two syndics and a procurator, who, though the executive power, have no votes in the senate. The lower house of assembly is chosen by the twelve guilds or companies of the free burgesses. The military force amounts to about 600 men of horse and foot.

The city of Lubeck, the capital of the republic, is situated in latitude 53. 50. 22. north, and longitude 10. 41. 32. east. It stands on a gentle elevation between the rivers Trave and Wakenitz, the former of which is navigable to the Baltic Sea, which it enters at Travemund, about twelve miles below the city. It has good wide streets, with massive houses, built in a very antique style. At present it displays a picture of decay when compared with the evident signs which remain of its former prosperity. After the battle of Jena in the year 1806, Blucher, with the wreck of the Prussian army, took refuge within the walls, and were followed by the French. A battle was fought in every street, which spread horror and a degree of suffering which has never been effaced.

The French, during their possession, robbed it of all that was moveable, and the trade on which it depended disappeared in the absence of the capital with which it had been carried on. The number of dwelling-houses is 3070, but that of inhabitants does not now exceed 23,000, a striking disproportion when the size of the houses is taken into consideration. The most prominent public building is the church of the holy virgin, with a magnificent altar of black marble, a most curious astronomical clock, and two towers 400 feet in height. The Rathshouse, in which the representatives of the Hans Towns assembled, with its extensive cellars, in better times stocked with many hundred pipes of the oldest Rhenish wine, all taken away by the French, is a fine old building. There is little trade, the chief part of which consists in the conveyance of goods from Hamburg to the ports of Sweden and Russia, and bringing back the products of those countries. There are some shipowners, and about ninety vessels, great and small, belonging to the port of Lubeck. There are some small establishments for making snuff and tobacco, for refining sugar, and for other smaller manufactures.

Lubeck is remarkable for what it has been, rather than for what it now is. It was once the head of a confederacy of cities, in which the spirit of freedom and of active commerce was carried on, whilst the rest of Europe was deeply sunk in military despotism and in disgraceful indolence. At that time it was respected, feared, and its alliance courted, by the monarchs of the most powerful states; and its powerful fleets overawed the whole of the shores of the Baltic Sea. As the history of this place is curious, a few lines may be devoted to it.

It appears that in the beginning of the ninth century a tribe of Sclavonians built on the little river Schwartau a fortified place to protect themselves against another tribe called the Obotrittens. This was the ancient Lubeck. It was, however, taken and made the residence of Henry king of the Obotrittens, who continued there till 1139, when it was captured and demolished, and the present city founded on the river Trave, by Rudolph of Holstein, and peopled by fugitives from Westphalia and the Netherlands. In the year 1158 it was transferred to Henry the Lion, duke of Saxony, who granted to the city those privileges which it long enjoyed, and which were gradually assumed by the other cities which had acquired independence. Their naval power then rose rapidly; and a war having broke out between the emperor of Germany and Henry, the citizens maintained the cause of the latter with so much resolution, that, though attacked, they only submitted in consequence of a treaty which insured to them all the rights and privileges they had previously enjoyed. The possession of the city then became an object of contest between Saxony, Holstein, and Denmark, by the last of which, in 1201, Lubeck was captured; but at length, in 1226, it threw itself under the protection of the empire, when Frederick the Second affirmed its freedom, and instated it as an imperial city, with all the privileges of an independent member of the Germanic body.

In 1241 the first alliance was formed with Hamburg, and in 1260 Bremen and other free cities had become members of the confederacy, of which Lubeck was declared the head, and the place of assembly of the whole representatives. This commenced the flourishing period of its existence, which long continued, till all the cities, excepting Lubeck, Hamburg, Bremen, and Frankfort, had been one after another subjugated, and united to the dominions of the several princes by whom they were surrounded. This had taken place towards the end of the sixteenth century, when the trade of Lubeck took another direction; and this place, though nominally the head of the remaining confederacy, was the poorest and least populous of any of them. In 1802, when so many German states lost their independence, Lubeck still nominally retained hers, till she fell under the French yoke in the year 1806. In 1810 Lubeck was formed into a portion of the French department of the Mouths of the Elbe, of which Hamburg was declared the capital. After the victory of Leipzig in 1813 its freedom was restored, and afterwards secured by the congress of Vienna in 1815. The restoration of its ancient power is now hopeless.

LUBIENIETSKI, Stanislaus, a Polish gentleman, descended from a noble family, and born at Cracow in the year 1623, was educated by his father with great attention. He became a celebrated Socinian minister, and took great pains to obtain a toleration from the German princes for his Socinian brethren. His labours, however, were ineffectual, and he was himself persecuted by the Lutheran ministers, and driven from place to place, until at length he was, along with his two daughters, banished out of the world by poison, his wife narrowly escaping, in 1675. He wrote a History of the Reformation in Poland, a Treatise on Comets, and some other works, in Latin.

LUBIN, Eilhard, was professor of poetry in the uni versity of Rostock in 1595, and ten years afterwards he was promoted to the professorship of divinity. He wrote notes upon Anacreon, Juvenal, Persius, and several other classics; but that which attracted the most notice was a treatise on the nature and origin of evil, entitled *Phosphorus de Causa prima et Natura Mali*, printed at Rostock in 1596, in which we find a curious hypothesis to account for the origin of moral evil. He supposed two coeternal principles, not matter and vacuum, as Epicurus did, but God, and *Nihilum*, or Nothing. This hypothesis being attacked by Grawer, was defended by Lubin; but, after all, he is deemed to have been better acquainted with polite literature than with divinity. He died in 1621.

LUBLIN, a province of Poland, on the right bank of the Vistula. It extends in north latitude from 50. 17. to 51. 43. and in east longitude from 21. 48. to 24. 2. It contains 7979 square miles, and 497,500 inhabitants. The Vistula is the boundary to the west, and the Bug divides it from Russia on the east. It has very extensive woods and some large marshes, but there are portions of considerable fertility. The capital is a city of the same name, situated on the river Bystryzca, the seat of a Catholic bishop, and, besides a cathedral, contains eighteen churches, a monastery, a college, 1829 houses, and 10,360 inhabitants. It has some manufactures of cloth and linen, and considerable trade during the fairs, one of which continues a month. Long. 23. 27. E. Lat. 51. 14. 30. N.

LUBNI, a circle of the Russian province of Pultowa, extending in north latitude from 48. 55. to 50. 27., and in east longitude from 32. 39. to 33. 33. The capital is the city of the same name, situated on the river Sula, 920 miles from St Petersburg. It is an open city, with three churches, a monastery, a veterinary college, 1000 houses, and 6130 inhabitants. Long. 32. 45. 25. E. Lat. 50. 0. 30. N.

LUC, JOHN ANDREW DE, a natural philosopher of great merit and celebrity, born at Geneva on the 8th of February 1727, was the son of James Francis de Luc, descended from a family which had emigrated from Lucca and settled at Geneva in the fifteenth century.

His father was the author of some very respectable publications in refutation of Mandeville and other sceptical writers; and he had the means of giving his son an excellent education, although he found it convenient to establish him in a commercial engagement, which principally occupied the first forty-six years of his life, without any other interruption than that which was occasioned by some journeys of business into the neighbouring countries, and a few scientific excursions among the Alps. During these, however, he collected by degrees, in conjunction with his brother William Antony, a splendid museum of mineralogy, and of natural history in general, which is still preserved at Geneva by the younger Deluc, his nephew. He at the same time took his share of the public business of the state, as one of the council of Two Hundred; and he is still remembered with respect by his fellow citizens, though he revisited them but once, and that for a few days only after his emigration, which was the consequence of some unexpected misfortunes in commerce. He bore them with fortitude, and he rather rejoiced than lamented at the change of his pursuits, when he removed to England in 1773. He was made a fellow of the Royal Society in the same year, and was appointed reader to the queen; a situation which he continued to hold for forty-four years, and which afforded him both leisure and a competent income. In the latter part of his life he obtained leave to perform several tours in Switzerland, France, Holland, and Germany. In this last country he passed six years, from 1798 to 1804; and after his return he undertook a geological tour through England. When he was at Göttingen, in the beginning of his German tour, he received the compliment of being appointed honorary professor of geology in that university; but he never entered upon the active duties of a professorship. He was also a correspondent of the Academy of Sciences at Paris, and a member of several other scientific associations.

His favourite studies were geology and meteorology. The situation of his native country had naturally led him to contemplate the peculiarities of the earth's structure, and the properties of the atmosphere, as particularly displayed in mountainous countries, and as subservient to the measurement of heights. He inherited from his father a sincere veneration for the doctrines of Christianity, and a disposition to defend the Mosaic account of the creation, against the prevailing incredulity of the age. His royal patroness was most anxious to encourage and promote his labours in this field; and he is universally allowed to have had great success in removing the specious objections which had been advanced by his antagonists, against the comparatively recent formation of the present continents. The testimony of Cuvier is sufficient to establish his character in this capacity, and to place him, at the same time, in the first rank of modern geologists. His original experiments relating to meteorology are, however, not less valuable to the natural philosopher; and he discovered many facts of considerable importance relating to heat and moisture. He noticed the disappearance of heat in the thawing of ice, about the same time that Black founded on it his ingenious hypothesis of latent heat. He ascertained that water was more dense about forty degrees of Fahrenheit than at the temperature of freezing, expanding equally on each side of the maximum; and he was the original author of the opinion since re-advanced by Mr Dalton, that the quantity of aqueous vapour contained in any space is independent of the presence or density of the air, or of any other elastic fluid; though it appears difficult to reconcile this opinion with some of the experiments of our author's great rival, Saussure, a philosopher who, as he very candidly allows, made, in many respects, more rapid progress in hygrometry than himself. Deluc's comparative experiments on his own hygrometer, and on Saussure's, show only that both are imperfect; but it may be inferred from them, that a mean between both would in general approach much nearer to the natural scale than either taken separately. It appears also probable that Saussure's is rather less injured by time than Deluc's, which has been found to indicate a greater degree of mean moisture every year than the last.

Deluc was a man of warm feelings, and of gentle and obliging manners, fulfilling on all occasions the various duties of a husband, a father, a master, and a friend; at the same time that his literary and scientific merits, and his unremitting attention to the service of the queen, insured her respect and her kindness. He saw her daily for many years, and in his last illness, which was long and painful, she showed him repeated marks of benevolent regard. He died at Windsor on the 7th of November 1817, leaving a variety of works, which will long be remembered in the scientific world.

1. Recherches sur les modifications de l'Atmosphère, 2 vols. 4to, Geneva, 1772; 4 vols. 8vo, Par. 1784. This contains many accurate and ingenious experiments upon moisture, evaporation, and the indications of hygrometers and thermometers, applied to the barometer employed in the measurement of the height of mountains.

2. Relation de différens Voyages dans les Alpes de Faucigny, 12mo, Maestricht, 1771. This relation was written principally by Dentand, who accompanied the two Delucs in these expeditions.

3. Account of a new Hygrometer, *Phil. Trans.* 1773, p. 404. Like a mercurial thermometer, with an ivory bulb,

which expanded by moisture, and caused the mercury to descend.

4. Rules for measuring Heights by the Barometer, *Phil. Trans.* 1771, p. 158. The first correct rules that had been made public.

5. Barometrical observations on the depth of the mines in the Harz, *Phil. Trans.* 1777, p. 401. Examples of the application of the rules.

6. An Essay on Pyrometry and Areometry, *Phil. Trans.* 1778, p. 419. A paper containing many valuable remarks on physical measures in general.

7. Lettres physiques et morales sur l'Histoire de la Terre, 6 vols. 8vo, Hague, 1778. Dedicated to the queen; relating particularly to the appearances of mountains, and to the antiquity of the human race; explaining the six days of the Mosaic creation as so many periods preceding the epoch of the actual state of the globe; and attributing the Deluge to the filling up of cavities supposed to have been left void in the interior of the earth. The whole work is intermixed with interesting observations on men and manners.

8. A second paper concerning some Barometrical Measurements in the Mines of the Harz, *Phil. Trans.* 1779, p. 485.

9. Lettres sur quelques parties de la Suisse, 8vo, 1781. Also addressed to the queen.

10. Nouvelles idées sur la Météorologie, 2 vols. in 3, 8vo, Lond. 1787. A very valuable collection of observations and experiments, including some original remarks on electricity.

11. Several papers on Hygrometry, on Vapour, and Rain, on Meteorology in general, on Expansion, and on Refraction, in Rosier's *Journal de Physique*, xxx. xxxii. xxxvi. xxxvii. xliii.

12. Some letters on the physical History of the Earth, in the *Monthly Review*, enlarged, especially June 1790, and vol. ii. appendix.

13. On Hygrometry, *Phil. Trans.* 1791, p. 1, 389. In one of these very important papers the whalebone hygrometer is described.

14. On Evaporation, *Phil. Trans.* 1792, p. 400. Amongst the fundamental principles laid down in this paper, the independence of vapour and air is asserted.

15. Lettres sur l'Histoire physique de la Terre, 8vo, Par. 1798. Addressed to Professor Blumenbach, and published by Mr Emery, a clergyman, at Paris. The substance had already appeared in the *Journal de Physique*, for 1790, 1791, and 1798. We find in this volume an essay written for a prize at Haarlem in 1791, but without success, on the existence of a General Principle of Morality. It contains an interesting account of some conversations of the author with Voltaire and Rousseau.

16. Lettres sur l'Education religieuse de l'Enfance, 8vo, Berlin, 1799.

17. Bacon tel qu'il est, 8vo, Berlin, 1800. Showing the bad faith of the French translator, who had omitted many passages favourable to revealed religion.

18. Précis de la Philosophie de Bacon, 2 vols. 8vo, Paris, 1802. Giving an interesting view of the progress of natural science.

19. Lettres sur le Christianisme, Berlin and Hanover, 1801, 1803. A correspondence with Mr Teller.

20. Introduction à la Physique terrêstre par les Fluides expansibles, 8vo, Par. 1803.

21. Traité élémentaire sur le Fluide Galvanique, 8vo, Paris, 1804.

22. A paper on Lavas, *Journal des Mines*, cxv. Nicholson, xx.

23, 24. Several articles in the *British Critic* and in the *Monthly Magazine.*

25. Traité élémentaire de Géologie, 8vo, Paris, 1809; also in English, by Delafite, the same year. This volume is less strictly introductory to geology than the *Lettres sur la Terre.* It is principally intended as a refutation of the Vulcanian system of Hutton and Playfair, who deduced the changes of the earth's structure from the operation of fire, and attributed a higher antiquity to the present state of the continents than is required in the Neptunian system adopted by Deluc after Dolomieu.

26. He sent to the Royal Society, in 1809, a long paper on separating the chemical from the electrical effects of the pile, with a description of the electric column and aërial electroscope, in which he advanced opinions so little in unison with the latest discoveries of the day, especially with those of the president of the society, that the council probably thought it would be either encouraging error or leading to controversy to admit them into the *Transactions.* He had, indeed, on other occasions shown somewhat too much scepticism in the rejection of new facts; and he had never been convinced even of Mr Cavendish's all-important discovery of the composition of water. The paper was afterwards published in Nicholson's *Journal* (xxvi.), and the dry column described in it was constructed by various experimental philosophers. It exhibited a continual vibrating motion, which was made more sensible by the sound of a little bell, struck by the pendulum at each alternation; and the vibration was more or less rapid, according to the state of the atmospherical electricity, and according to other circumstances affecting the column; but the motion ceased at last, after a continuance of several months, or perhaps years. There are also papers in volumes xxi. xxii. xxvii. xxviii. xxxii. xxxiii. and xxxv. mostly on electricity and galvanism, together with one on hygrology, a letter to Bode on comets, and a fanciful theory of the origin of the heat derived from compression. Some of them are dated from Ashfield, near Honiton, in Devonshire.

27. In the *Philosophical Magazine*, volumes xxxv. xlii. xliii. and xlv. there are also some papers on electricity and geology, especially on that of St Michael's Mount, of Vesuvius, and of Northumberland; and a note on the sympathetic vibrations of the pendulums of two clocks placed near each other.

28. Geological Travels in the north of Europe, 8vo, Lond. 1810.

29. Geological Travels in England, 2 vols. 8vo, Lond. 1811.

30. Geological Travels in Switzerland and Germany, 2 vols. 8vo, Lond. 1813.

31. An Abridgment of Geology, published in 1817, when he was in his ninetieth year, is mentioned as one of his best works; but it seems to have been only a republication or a translation of some former treatise, perhaps the *Traité Elémentaire.*

(*Philosophical Magazine*, November 1817; Monod and Weiss, in the *Biographie Universelle*, tome xxv. 8vo, Paris, 1820.) (L. L.)

LUCANAS, a province of Peru, in South America, bounded on the north by the province of Castro Vireina, on the east by Parina Cochas, and on the south and west by Camana. It is 180 miles in length, and varies from thirty-six to ninety in breadth. It is situated amongst the craggy rocks of the Cordilleras; and the temperature is very cold, but the soil is fertile. The chief grains cultivated are wheat, barley, and maize; and in the valleys fruits are grown with considerable success. It has some silver mines, which are supposed to be the richest in Peru, and to which the province owes its chief importance. Its capital is a small place of the same name, situated in latitude 14. 58. south.

LUCANIA, a country of Italy, and a part of Magna Græcia, being bounded on the north by the river Silarus, by which it was separated from the Picentini, and by the river Bradanus, by which it was parted from the Apuli Peucetii; on the south by the Laüs, which separated it from the Bruttii; on the east by the Sinus Tarentinus; and on the west by the Tuscan Sea.

LUCANUS, M. Annæus, a celebrated Latin poet, who was born at Corduba, now Cordova, a city of Bætica, the southern province of Spain, A. D. 38, the year after the accession of the Emperor Caligula. He was the son of Annæus Mela, a Roman knight of considerable reputation, and the brother of the philosopher Seneca. The young Lucan, educated at Rome in the doctrines of the Stoic philosophy by Annæus Cornutus, displayed at an early age great poetical talents. His uncle Seneca, the preceptor of Nero, made him acquainted with that prince, who, admiring his nume-ous acquirements, raised him to the quæstorship before the usual age, loaded him with favours, and even honoured him so far as to enter the lists of literary competition against him. Lucan sung the descent of Orpheus to the infernal regions, Nero the metamorphosis of Niobe; and it is said that Lucan, forgetful of his duties as a courtier, carried off the palm of victory, and thereby lost the favour of the emperor (Stat. *Silv.* ii. 7, 58). It is impossible to fix the period when he composed those adulatory verses which disgrace the beginning of the Pharsalia; but, from their disgusting servility, we might be inclined to suppose that they were addressed to a tyrant who was well known and feared. According to an ancient tradition, one of these verses had already prepared the emperor to take umbrage at any thing that had the appearance of an insult. Nero uinted, and was deeply offended at the verse,

> Unde tuam videas obliquo sidere Romam.

All these various circumstances excited the wrath of the tyrant; and when Lucan, having composed a poem on the burning of Troy and on that of Rome, requested permission to read it at the public theatre, according to the custom of those times, this favour was denied him. Such persecution irritated the poet, and induced him to join a conspiracy against the emperor, which was composed of all the best citizens of Rome. It was, however, discovered before it could be carried into execution; and many of the conspirators were arrested and put to the torture. It is said that Lucan, on promise of his life, denounced his associates, and was base enough even to name his own mother.

Such conduct, however, does not appear to have procured for him forgiveness, as the only favour granted was the choice of his mode of death. In his last moments Lucan recovered his firmness of mind, and, opening his veins in a warm bath, allowed himself to bleed to death, whilst he is said to have repeated his own description (*Pharsalia*, iii. 637) of the death-scene of a young warrior who has been wounded by a serpent.

> Scinditur avulsus; ruptis cadit undique venis,
> Discursusque animæ diversa in membra meantis
> Interceptus aquis. Nullius vita perempti
> Est tanta dimissa via. Pars ultima trunci
> Tradidit in letum vacuos vitalibus artus.

He died at the age of twenty-seven, in the year 65 of our era, leaving a wife, Polla Argentaria, one of the most remarkable women of her time (Tacit. *Ann.* xv. 49, 56, 71; Sidon. Apollinar. ii. Ep. 10).

Lucan was the author of many works which have not come down to us, particularly the Burning of Troy, the Burning of Rome, the Descent of Æneas to the Infernal Regions, Ten books of Sylvæ, Medeia an imperfect tragedy and Epistles, one of which, in praise of Calpurnius Piso, has been preserved; but the work for which he is most celebrated is his poem entitled *Pharsalia*, in ten books, which he did not live to finish. The subject of the poem is the war between Cæsar and Pompey, from its commencement to the siege of Alexandria. Lucan adheres closely to chronological order in his narrative, and scarcely deviates from historical truth in his account of the various transactions. From the little scope he allows to his imaginative powers, some critics have thought that Lucan should not be considered as an epic poet, but ranked amongst historians. His poetical merits have in all ages been fiercely contested; some considering him equal to Virgil and Ovid, whilst others have placed him in the lowest rank of poets. The judgment of posterity, however, is without appeal, and it has long stamped the character of the poem as cold and declamatory, notwithstanding that there are many passages full of genuine poetry. The style is by no means uniform, and even the political sentiments of the author vary in different parts of the work. In the first three books his love of freedom is scarcely to be discovered, and every opinion is suppressed which was likely to have offended Nero. In the remainder of the poem, as his hatred increased against Nero, we can trace his aspirations after freedom gradually growing stronger. There seems no good reason for believing that the poet had any great moral end in view, except perhaps that he wished to excite in the breasts of his countrymen a love of freedom, by exhibiting before their eyes the last contest which their ancestors had maintained in its defence. He wished also, perhaps, like the historian Livy, to forget the fearful images of the present, by occupying his mind with, and dwelling on, the past. His want of a glowing imagination and of inventive genius is somewhat counterbalanced by powerful and energetic language, by a disdain of every thing that is mean or grovelling, and by noble thoughts, which are uttered with all the dignified seriousness of a Stoic. There are many editions of this work, but one of the best is that of Burmann (Leyden, 1740), and the last is that by C. F. Weber, in 3 vols., the last of which contains some valuable scholia (Leipzig, 1828).

LUCAR, St, de Barrameda, an unwalled Spanish city, at the mouth of the Guadalquiver, in the province of Seville, with 5000 inhabitants, one silk and two hat manufactories, and one tannery.

Lucar, St, de Guadiana, a Spanish fortified city on the Guadiana, in the province of Seville, with 2800 inhabitants, and a good haven, whence steam-boats now pass constantly to Seville.

LUCARIA, a feast celebrated at Rome on the 18th of July, in memory of the flight of the Romans into a great wood, where they found an asylum, and saved themselves from destruction. This wood, in which they found protection, was situated between the Tiber and the *Via Salaria.* The enemies from whom the Romans fled were the Gauls. On this festival Plutarch tells us that it was customary to pay the actors, and such as contributed to the public amusement, with the money arising from the felling of wood; and this money was called *lucar.* It is obvious, from what has been observed, that *lucar* and *lucaria* are derived from *lucus*, a grove.

LUCAS Jacobs, an eminent artist, and more generally known by the name of *Lucas van Leyden*, was born at Leyden in 1494. He received his first instructions in the art of painting from his father Hugues Jacobs, but completed his studies in the school of Cornelius Engelbrecht. He gained much money by his profession; and being of a generous turn of mind, he spent it freely, dressed well, and lived in a superior style. It is said that a few years before his death he made a tour in Zealand and Brabant; and that, during his journey, a painter of Flushing, envious of his great abilities, gave him poison at an entertainment, which, though very slow in its operation, proved fatal in its effect, and put an end to his life, after languishing six years under its cruel influence. Others deny the story of the poison, and attribute his death to his incessant industry. The superiority of this artist's genius manifested itself in his infancy; for his works, even from the age of nine, were so excellent, as to excite the admiration of all contemporary artists; and when he was about fifteen, he painted a St Hubert which gained him great applause. His tone of colouring is good; his attitudes, making allowance for the stiff German taste, are well chosen; his figures have considerable expression in their faces, and his pictures are very highly finished. In the town-hall at Leyden, the most capital picture of Lucas, the subject of which is the Last Judgment, has been preserved with great care; the magistrates having refused very large sums which have been offered for it. This artist painted not only in oil, but also in distemper and upon glass. Nor was he less eminent for his engraving than for his painting. He carried on a familiar and friendly correspondence with Albert Durer, who was his contemporary; and it is said, that as regularly as Albert Durer published one print, Lucas published another, without the least jealousy on either side, or any wish to depreciate each other's merit. His style of engraving, however, according to Mr Strutt, differed considerably from that of Albert Durer, and seems evidently to have been founded upon the works of Israel van Mechlen. His prints are very neat and clear, but without any powerful effect. The strokes are as fine and delicate upon the objects in the front as upon those in the distances; and this want of variety, joined with the feebleness of the masses of shadow, give to his engravings, with all their neatness, an unfinished appearance, much unlike the firm substantial effects which we find in the works of Albert Durer. He was very attentive to the minutiæ of his art. Every thing is carefully made out in his prints, and no part of them is neglected. He gave great character and expression to the heads of his figures; but on examination of his works we find the same heads too often repeated. He engraved upon wood as well as upon copper, but his works on the former are by no means numerous. They are, however, very spirited, though, upon the whole, not equal to those of his friend Albert. The prints of this master are pretty numerous, but very seldom met with complete, especially fine impressions of them; for though they are, generally speaking, executed with the graver only, yet, from the delicacy of the execution, they soon suffered in the printing.

Lucas, *Richard*, a learned English divine, was born in 1648, and studied at Oxford, after which he entered into holy orders, and was for some time master of the free school at Abergavenny. Being esteemed an excellent preacher, he became vicar of St Stephen's, Coleman Street, London, and lecturer of St Olave's, in Southwark. He was created doctor of divinity, and in 1696 installed prebendary of Westminster. His sight began to fail in his youth, and he totally lost it in his more advanced age. He was greatly esteemed for his piety and learning, and published several works, particularly, 1. Practical Christianity; 2. An Inquiry after Happiness; 3. Several sermons; and, 4. A Latin translation of the Whole Duty of Man. He died in 1715.

LUCCA, a dukedom in Italy, extending in north latitude from 43. 46. to 44. 14., and in east longitude from 10. 3. to 10. 44. It has enclosed within it a small portion of Tuscany, and has the communes of Menuciano, Albiano, and Renzano separated from it, between the territories of Modena and Tuscany. It comprehends 440 square miles, with one city and 290 towns and villages, which are inhabited by 150,000 persons, being the most dense population of any state in Europe. It is bounded on the north by Modena and Tuscany, on the east and the south by Tuscany, and on the west by the Mediterranean Sea. The Apennines form the northern part of the duchy, and extend from Monte Guiliano to the sea, gradually declining in height as they proceed to the westward. The other parts are level, and of high fertility. The river Serchio is the only considerable stream, and, by the numerous canals connected with it and employed in irrigation, is one of the chief causes of the great power of production which the soil displays. The agriculture of Lucca is most admirably conducted. The plains and valleys appear like gardens, in which corn and pulse fields are intermingled with olive plantations and fruit trees. The hedges are filled with elm, mulberry, and other trees, around which the vines are to be seen clustering in elegant festoons. Along the shore are rich meadows, on which numerous horned cattle are fed, whilst near them other fields exhibit most abundant crops of rice. Even the mountains almost to the summits are covered with vines, or with olive, chestnut, and mulberry trees; and the Apennines themselves produce chestnuts, as well as the finest pines and larches. Notwithstanding the application of all the labour to agriculture, the duchy does not produce corn equal to the consumption, but receives it from the other states in exchange for the oil and silk, which is abundantly obtained. As the kind of agriculture practised engages all the labour, scarcely any of it is directed towards manufactures; and even the silk, except that used for internal purposes, is not organized, but is exported in the raw state. The executive government of Lucca was conferred, by the congress of Vienna, on the Empress Maria Louisa, the wife of Napoleon. The power of making laws is intrusted to a senate of thirty-six members, who meet for a month every year. The revenue of the duchy is from L.60,000 to L.70,000 annually, of which the civil list of the regent is L.12,000. The military force is composed of from 1000 to 1200 men. The capital is the city of the same name, situated on the canal of Ozzorti, which joins the river Serchio. It is walled, and contains the palace of the regent, an old Gothic cathedral, a university, and some other institutions for education, three hospitals, and 17,450 inhabitants. There are some respectable manufacturers of woollen cloths and casimeres. The environs are adorned by many villas, and are cultivated with the minute attention which is usually paid to gardening. Long. 10. 12. E. Lat. 43. 49. N.

LUCERA, a city of the province Capitanata, in the kingdom of Naples. It is situated on a hill on the edge of the plain of Puglia, is surrounded with walls, and is the see of a bishop. The cathedral is supported by fourteen beautiful marble columns. It has twelve other churches, several convents, and 8325 inhabitants.

LUCERES, in Roman antiquity, the third in order of the three tribes into which Romulus divided the people, including all foreigners, and so called from the *lucus* or grove where Romulus opened an asylum.

LUCERIUS, in *Mythology*, a name given to Jupiter, as *Luceria* was given to Juno, these being considered as the deities who gave light to the world.

LUCERNA, one of the valleys of Piedmont, which is inhabited by the Vaudois. The capital, of the same name, is situated on the river Pellice, and contains about 1100 inhabitants. The whole valley has a population of 12,000, who adhere to the faith of their ancestors, who separated from the Roman Catholic church several centuries before the reformation of Luther.

LUCERNE, a canton in the centre of Switzerland, being surrounded by Arau, Schweitz, Unterwalden, Zug, and Berne. It is 792 square miles in extent. The southern part is covered with a portion of the lofty Alps, but the whole is elevated, the lake of the four forest cantons being 1320 feet above the level of the sea. There are, however, some extensive plains, with well-cultivated fields, which produce corn, potatoes, and, from the dairies, a great deal of butter and cheese. It is one of the cantons which produce more food than they consume. It is a highly picturesque country, from the height of its mountains and the rapidity and clearness of its streams. The inhabitants amount to about 100,000, chiefly adhering to the Romish church. A great portion of the land belongs to the church and other corporate bodies. The taxes to the state are lower than in the other cantons. The constitution is that of an aristocratic republic, with a senate composed of sixty-four members chosen for life, and thirty-six for a shorter period. The canton is divided into three bailiwicks. The capital, of the same name, is built at the efflux of the river Reuss from the lake of the four forest cantons, or of Lucerne. It is surrounded with walls and towers, and contains five churches, two convents for men and two for females, 620 houses, and 5000 inhabitants. It has a lyceum, a gymnasium, and other schools. The inhabitants are active manufacturers of hats and hosiery, of printed calicoes, of leather, beer, vinegar, and some smaller articles, and carry on the chief trade of the canton, by means of which wine, sugar, coffee, and other foreign articles are disposed of. Long. 0. 13. 15. E. Lat. 47. 3. 27. N.

LUCIA, St, one of the Caribbee Islands, in the West Indies, situated in latitude 13. 37. north, and longitude 60. 58. west. It is about thirty-two miles in length and twelve in breadth, and is divided longitudinally by a ridge of lofty hills, from 1200 to 1800 feet in height, clothed with the finest timber. Its appearance from the sea is very striking, presenting great diversity of scenery. At its southern extremity are two mountains of volcanic origin, called the Sugar Loaves, which rise perpendicularly from the sea to a great height, in the form of parallel cones, tapering towards the summits. They are covered with evergreen foliage, and form the entrance into a small but deep and beautiful bay. The mountains, which run north and south throughout the island, are of volcanic formation, and assume the most fantastic shapes, abounding in deep chasms and pointed eminences. They are completely covered with wood, which attracts the clouds, and the island is consequently deluged with rain nine months out of the twelve. This is the reason why the climate is so unhealthy; but it will become less so in proportion as the woods are cut down, and the morasses and stagnant waters drained off. At the foot of the mountains there are numerous small lakes, in which the water is perpetually boiling, and in some places the ebullition is so violent that the water is thrown up to the height of four or five feet. The valleys throughout the island, as well as the plains upon the coast, are fertile, and under good cultivation, being well watered by numerous rivulets. The island is divided into two territories; Basseterre, the low or leeward territory, which is well cultivated, and the most populous, though the prevalence of stagnant waters and morasses renders the climate very unhealthy; and Capisterre, the high or windward territory, which is also very unhealthy, but is becoming less so as the wood on the high lands is cleared away. These territories are divided into three districts, which are again subdivided into ten parishes, the aggregate population of which, in 1832, amounted to 22,743. The inhabitants are, for the most part, engaged in agricultural pursuits. The principal stock in the island consists of 676 horses, 2421 horned cattle, 1616 sheep, and 765 goats.

This general description will be better understood from the following statistical tables, relative to the population, the produce, the shipping attached to the island, and the number of seamen employed.

Return of the Free Population, Births, Marriages, and Deaths, in the year 1832.

Whites.		Free Blacks.		Aliens and Resident Strangers.	Persons employed in			Births.	Marriages.	Deaths.
Males.	Females.	Males.	Females.		Agriculture.	Manufactures.	Commerce.

Return of the Produce, &c. in 1832.

Crops.								Produce.				
Nature of the Crops, and Number of Acres of Land in each Crop.								Nature of the Produce, and Quantity of each.				
Canes.	Coffee.	Cocoa.	Cotton.	Provisions.	Pastures.	Total Number of Acres in Crop.	Number of Acres of Uncultivated Land.	Sugar.	Coffee.	Cocoa.	Rum.	Molasses.
Acres.	Acres.	Acres.	Acres.	Acres.	Acres.			lbs.	lbs.	lbs.	Gallons.	Gallons.
3641½	407⅓	176	14	2964	4286¾	11,489½	21,313¾	5,061,500	87,520	26,277	67,202	135,692

From this return, it appears that the number of acres in the island is 32,803¼; but, as the upper part of the hilly country has not been taken into account, the total number cannot be less than 37,500 acres.

The Shipping attached to the Island, and the Number of Seamen employed, are as follows.

Places.	Inward.			Outward.		
	Ships.	Tons.	Men.	Ships.	Tons.	Men.
Great Britain	11	2,443		11	2,518	
British colonies	124	5,250		131	6,903	
United States	17	2,056		15	1,731	
Foreign States	230	6,194		284	7,294	
Total	382	15,943	2,106	441	18,446	2,433

The value of the merchandise imported into the colony in 1832 was L.35,958, and the exports from it the same year amounted to L.51,126. The authorized coins in circulation are British, Spanish, and French. The weights in use are the French pound and quintal.

The taxation, which amounts to nearly L.10,000, falls very heavily on the producers, and is much complained of.

St Lucia was first settled by the English about the year 1635, and belonged alternately to France and England, till 1803, when it was finally captured by the English. The white inhabitants are generally French, who profess the religion, speak the language, and possess the manners of that country, but who maintain little intercourse with the English residents. Their affairs are administered by a governor and council, with French laws where these are not adverse to the British.

The only town in the island is Castries, which is situated in a long and winding bay of the same name. It is a small, mean place, and very unhealthy, but possesses an excellent harbour. The fort is situated about two miles from the town, on the summit of a hill called Mornefortune. On the west coast there is an excellent harbour called the Little Careenage, accessible at the entrance to only one vessel at a time, but capable within of containing thirty ships of the line. Nearly six miles from the harbour of St Lucia, is a small island called Pigeon Island, about half a mile long and a quarter broad. It is of some importance as a military station, from its commanding a view of every ship which enters or departs from the adjacent island of Martinique. It is, moreover, valuable for a very fine and extensive anchorage between it and the northern part of St Lucia. The climate is the most salubrious in that quarter.

Lucia, *St*, a city of the island of Sicily, in the kingdom of Naples, situated on a river of the same name in the province of Demone, 190 miles from Palermo. It is in a healthy situation, on the declivity of the mountain Dinnamane, and contains 6000 inhabitants.

LUCIANISTS, or **Lucanists**, a religious sect, so called from Lucianus, or Lucanus, a heretic of the second century, and a disciple of Marcion, whose errors he followed, adding to them some new ones of his own. But Epiphanius says he abandoned Marcion, teaching that people ought not to marry, for fear of enriching the Creator; and yet other authors mention that he held this error in common with Marcion and other Gnostics. He denied the immortality of the soul, asserting that it was material, and consequently dissoluble. There was another sect of Lucianists, who appeared some time after the Arians, and who taught that the Father had always been a father, and that he had the name even before he begot the Son, as having in him the power or faculty of generation. In this manner they accounted for, or rather impugned, the eternity of the Son.

LUCIANUS, a celebrated Greek writer, was born at Samosata, the chief city of Commagene, a district situated upon the right bank of the river Euphrates. The precise dates of his birth and death are unknown; but it seems to be generally allowed that he flourished during the reign of the Antonines and of Commodus. Reitz, who has examined this point with much minuteness, makes his life extend between the years 120 and 200 of our era. His own writings supply us with what scanty information we have respecting his private history. His parents, he tells us, were poor, and found it necessary that their son should at an early period choose the profession by which he was to gain his livelihood. His maternal uncle was a sculptor of some fame at Samosata, and was willing to teach his nephew his own profession; but the youth having contrived awkwardly to break a marble slab which he was set to polish, received a severe beating from his cross-grained uncle. Lucian refused to submit to such treatment, and gave up all thoughts of succeeding to the lucrative business of his uncle. He then turned his attention to a more liberal profession, and devoted himself to the study of law; but becoming disgusted with the chicanery and deceit of which he was obliged to be cognisant, he abandoned his new profession, and applied himself to philosophy. He then visited the different parts of the civilized world; he resided several years in Gaul and in Italy, of which he gives an account in his treatises entitled *Nigrinus*, but chiefly in Athens, where he became thoroughly master of the Greek language. It is believed, from incidents mentioned in *Nigrinus* and *Hermotimus*, that Lucian approached his fortieth year when he left Gaul, where he appears to have resided from ten to fifteen years. Massieu imagines that he returned to Samosata, and remained in his native place till Marcus Aurelius conferred upon him a lucrative situation in Egypt. Wieland, however, who examined this part of his life minutely, gives satisfactory reasons for believing that he spent most of his time at Athens, where he composed the greater part of his finest dialogues. He was certainly resident in Greece A. D. 165, where he witnessed the self-sacrifice of the enthusiast Peregrinus Proteus on the funeral pile, during the celebration of the Olympic games. He spent the latter part of his life in Egypt, but he does not state the precise nature of the office which he filled in that country.

Lucian is distinguished as a writer for fertility of genius, wit, taste, and elegance, and for the talent of conferring the grace of novelty upon the most common and familiar topics. Notwithstanding the great change in customs and manners, after a lapse of seventeen hundred years, the wit of Lucian is still amusing, his satire still applicable, and his pictures of manners still fresh and vivid. It must be confessed that he sometimes exceeds reasonable bounds whilst he ridicules the absurd superstitions of his countrymen, and laughs at the mountebanks who were decked out with the name of philosophers. Whilst he merely intends to attack superstition, he is often so carried away by his wit as to ridicule all religious sentiments. He strikes at the very foundation of morality; and the blows which he aims at the hypocrites amongst philosophers, sometimes fall on the good and virtuous. In depicting the manners of the vicious, he is at times obscene and licentious. Amongst the most spirited of his works we may mention, the *Dialogues of the Gods*, in which Lucian makes the gods converse, as it were, in their domestic capacity and undress, and in moments of weakness, when, not being aware that they were privily overheard by men, they exposed themselves to the view of their worshippers in all their nakedness. In these dramatic scenes they show themselves, by their follies, baseness, and vices, unworthy of the esteem and confidence of mankind. *Dialogues of the Dead*, in which he ridicules with his peculiar humour the vulgar tenets respecting the state of souls after death, hell-torments, and the deification of dead persons. *Timon*, in which there is considerable resemblance to the *Plutus* of Aristophanes; the *Dream of Micyllus*, or *the Cock; Jupiter Tragœdus*, the comic title of a little drama of much wit and humour, in which Jupiter gets such serious wounds as he has never since been able to recover. *The Convicted Jupiter*, in which Lucian shows the inconsistency of the pagan doctrines concerning fate, the providence of the gods, and the rewards and punishments after death. *The Sale of the Philosophers*, in which he exposes the absurd tenets, manners, and principles of every sect. *The Angler*, or *the resuscitated Philosophers.* In the story of *Lucius*, or the *Enchanted Ass*, there are several indecent and licentious scenes, though it abounds with humour. This story has been ascribed by some to Lucius of Patræ, and there seems good reason for believing that Lucian merely abridged it; but no one has ever doubted his claim to the story entitled *The True History*, a long tissue of incredible adventures, and extraordinary voyages made in seas full of wonders. His intention was to ridicule the impostures which Etesias and Iambulus had attempted to palm upon the world as true stories. The tract entitled *How to write History* has been unanimously pronounced one of the best and most instructive of his writings. There have been numerous editions of the works of Lucian. The first was published in 1496; but the best is that of Hemsterhuys and Reitz, Amsterdam, 1743, three vols. 4to, to which is added a fourth volume, *Lexicon Lucianeum*, by Conrad Reitz, 1746. It has been translated into German by Wieland, into Italian by Gozzi, and into English by Franklin (1780), and Tooke (1820).

LUCIFER, according to the poets, was the son of Jupiter and Aurora. In astronomy, Lucifer is the planet Venus, which either goes before the sun in the morning, and is our morning star; or in the evening follows the sun, and then is called *Hesperus* or the evening star.

LUCIFERA, in *Mythology*, a surname given to Diana, under which title she was invoked by the Greek ladies in childbed. She was represented as covered with a large veil, interspersed with stars, bearing a crescent on her head, and holding in her hand a lighted flambeau.

LUCIFERIANS, a religious sect, who adhered to the schism of Lucifer, bishop of Cagliari, in the fourth century, who was banished by the Emperor Constantius for having defended the Nicene doctrine concerning the three persons in the Godhead. St Augustin seems to intimate that the Luciferians believed the soul, which they considered as of a carnal nature, to be transmitted to the children from their fathers. Theodoret says that Lucifer was the author of a new error. The Luciferians increased mightily in Gaul, Spain, Egypt, and other countries. The occasion of the schism was, that Lucifer would not allow any acts he had done to be abolished. There were only two Luciferian bishops, but a great number of priests and deacons. The Luciferians cherished a peculiar aversion to the Arians.

LUCILIUS, Caius, a Roman knight, who is generally considered as the inventor of satirical composition, at least of that new form which was adopted by Horace, Persius, and Juvenal. Of his personal history we can collect only a few facts. He was born 148 B. C. at Suessa, now *Sessa*, a city of the Aurunci, in Latium, and died at Naples at the age of forty-six, B. C. 103 (Juv. i. 20; Euseb.). He attended Scipio Africanus in the war against Numantia, B. C. 134, at an age when he could scarcely be expected to serve in arms. It was then that he acquired the friendship of the younger Scipio, and of Lælius (Vell. Pat. ii. 9). He composed thirty satires, epodes, hymns, a comedy, and a Life of Scipio the elder. His satires are frequently mentioned by ancient writers, and with great praise; but we have only a few fragments remaining. Lucilius first introduced hexameter verse, which became the usual measure of Roman satirical compositions; and made little use of the iambus or trochæus. He also excelled those who preceded him, in the sharpness of his wit and the polished smoothness of his language. Horace, however, pronounces a severe sentence on the poetry of Lucilius. He finds his verses harsh and unmusical, and compares him to a river whose waters bring down particles of gold and mud mingled together (*Sat.* i. 10). The fragments of Lucilius have been published by Douza, with learned notes, Leyden, 1597, and Amsterdam, 1661; again by Volpi, Padua, 1735. (See Bähr, *Geschichte der Romischen Literatur*, Carlsruhe, 1832.)

LUCIMETER. This name has been given to an apparatus employed by Bouguer for measuring the intensity of the light which proceeds from different bodies.

In the case of two lamps or candles burning near to each other, the intensity of the light may be compared, by comparing the intensity of the shadows of an adjacent body. The shadow produced by interposing the body in the stronger light is darker than its shadow formed by the interposition of the body in the rays of the weaker; because the first shadow is enlightened only by the light it receives from the weaker light, whilst the other shadow is more strongly enlightened by the light from the stronger light. But this method will not serve for comparing the intensity of the light of the sun and moon, for the light of the sun so greatly exceeds that of the moon, that when both are visible at the same time, the light of the moon is far too weak for any shadow to be formed by intercepting it.

For the purpose of measuring and comparing the intensity of the light of the sun and moon, Bouguer reduced the light of the sun and of the moon till the light appeared to be equal to that of a candle. The eye is able to judge whether or not two lights are equal; but if the lights are unequal, it is impossible to estimate by inspection how much the one exceeds the other. Being able to calculate how much he had reduced the light of the sun and of the moon, he was enabled to say what proportion their light bore to that of the candle.

For the former, Bouguer, when the sun was at an elevation of thirty-one degrees above the horizon, received the light into a dark room, through a hole of one twelfth of an inch in diameter. In this hole was placed a concave glass to weaken the light, by making the rays diverge more than they would in passing through the hole without a concave glass. He received the image formed by the divergent rays at a distance of five or six feet, by interposing a screen, which formed a right section of the cone of divergent rays. This right section was a round image of the sun, of $\frac{108}{12}$ of an inch in diameter; therefore the light was diminished by the square of that number, since the light received through a hole of one line in diameter was diffused over a circle of 108 lines in diameter, and of 1164 times the area. This light he found to be equal to that of a candle placed at a distance of sixteen feet.

He employed the same concave glass to receive the light of the full moon, the moon being nearly at its mean distance from the earth, and at thirty-one degrees of altitude, the same altitude as the sun had in his observations of that luminary. The light of the moon being weak, he received the image at eight twelfths of an inch from the concave glass, and then the light of the image was so weak as to be equal to the light of a candle at the distance of fifty feet.

Now the light of the moon was diminished in the proportion of the square of one to sixty-four, which is the square of the diameter of its circular image. If the light of the moon had been diminished 11,664 times, it would have been equal to the light of the candle removed to a distance of 675 feet; for as eight, the diameter of the image, is to fifty, the distance, so is 108, the diameter of the image when the light is reduced 11,664 times, to 675 feet, the distance of the candle which would produce that degree of light. Therefore the light of the sun being equal to that of a candle placed at the distance of sixteen inches, and the light of the moon being equal to the light of the same candle placed at the distance of 675 feet, that is, 8100 inches, it follows that the light of the sun is to the light of the moon as 65,610,000, the square of 8100, is to 256, the square of 16. This experiment gave the light of the sun 256,289 times greater than the light of the full moon. Bouguer obtained results somewhat different from other experiments, and taking a mean of these results, he concludes that the light of the sun is 300,000 times greater than the light of the full moon. The light of the moon, when collected into a focus by a concave mirror which condenses the light into a space 306 times less than the natural state of the light, produces no sensible heat.

Bouguer found, by a process similar to that above described, that the light of the full moon when elevated 66° 11′, was to the light of the full moon elevated 19° 16′ above the horizon, as 2500, the square of 50, to 1681, the square of 41. The sun at the harbour of Croisac in Bretagne, where Bouguer made his experiments, has the same apparent altitudes of 66° 11′, and 19° 16′ at the summer and winter solstices; and he concludes that the intensity of the light of the sun at the summer solstice is to the intensity of its light at the winter solstice, in the above-mentioned ratio of 2500 to 1651, or about three to two. He found that the light of the moon, when near the horizon, and about to set, was 2000 times less than the light of the moon elevated 66° 11′. This difference in the light of heavenly bodies when at different altitudes proceeds from the want of transparence in the air; for when the heavenly body is not much elevated above the horizon, the rays proceeding from it have a greater distance of atmosphere to pass through than the rays from the same body at a greater altitude; and the rays from a heavenly body in the zenith proceed in the direction of a diameter, and therefore traverse the atmosphere by the shortest path. Bouguer calculates that the mass of air passed through by the rays from a heavenly body at 66° 11′ is equal to a supposed mass of air of the uniform density of the air at the surface of the earth, 4275 toises in thickness; and that the mass of air passed through by the rays from a heavenly body 19° 16′ in altitude, is equal to a supposed mass of air of the density of the air at the surface, and of 11,744 toises in thickness.

He concludes that light is diminished $\frac{819}{2500}$, or about one third, by passing through a mass of air of the uniform density of the air at the surface, and 7469 toises in thickness. The rays from a heavenly body near the horizon are likewise impeded by the terrestrial vapours, which vary in density, and render the intensity of the light of a heavenly body at the horizon various at different times. The same cause renders the quantity of the refraction of the heavenly bodies at the horizon uncertain.

In certain states of the air, the discs of the sun and the moon, when at the horizon, appear somewhat elliptic, the apparent vertical diameter being less than the horizontal. This is occasioned by the greater refraction of the air through which the under limb is seen; which refraction elevates the apparent place of the under limb by a quantity sensibly greater than that quantity of refraction by which the upper limb is raised. This alteration of figure, and the colour of the rising and setting sun and moon, indicate the greater or less quantity of vapour diffused in the air, and are usefully referred to by the seaman and farmer as prognostic indications of the weather.

The existence of a greater or less quantity of vapour mixed with the air is also indicated by the different degrees of intensity of the blue colour of the sky. Some are of opinion that this colour depends on the colour of the mass of air which forms the atmosphere; others maintain that it arises from the darkness of space seen through the interposed atmosphere. The blue colour of the sky increases in intensity from the horizon to the zenith, and is particularly intense when seen from the elevated parts of the Alps, because in that situation there are few terrestrial vapours mixed with the air, and it is the white colour of these vapours which renders the blue less intense in lower situations. For the purpose of estimating and noting its intensity, it is compared with different tints of blue painted on a card, as described under the article CYANOMETER.

See *Essai d' Optique sur la Gradation de la Lumière*, par Bouguer; and *Voyage* de Humboldt, *Relation historique*, chap. iii. p. 251. (B. B.)

LUCINA, a goddess amongst the Romans, who presided over women in labour. Some take her to be Diana, and others Juno. She was called *Lucina*, because she brought children to the light; from the Latin word *lux*, light.

LUCKENWALDE, a city of the province of Brandenburg, in Prussia, situated on the river Nuthe. It contains 680 houses, and 4150 inhabitants, who are employed chiefly in making cloth, and other woollen goods.

LUCKNOW, a city of Hindustan, in the province of Oude, situated on the south bank of the river Goomty, over which there are two bridges, one a very noble Gothic edifice of stone, and the other a platform laid upon boats, and merely connecting the King's Park with the palace. The Goomty is navigable for boats of a common size at all seasons of the year, and falls into the Ganges between Benares and Gazypoor. The last sovereign, Saadut Ali, had brought over an iron bridge from England, and a place was prepared for its erection; but, on his death, his successor declined prosecuting the work, on the ground that it was unlucky; so that it is now left to be destroyed with rust. The streets where the lower classes reside consist of mean houses built of clay, "with the filthiest lanes between them," says Bishop Heber, "that I ever went through, and so narrow that we were obliged to reduce our front, and even a single elephant did not pass very easily. A swarm of beggars," he continues, in the lively description which he gives of the aspect of the town and its population, "occupied every angle, and the steps of every door, and all or nearly all the remaining population were, to my surprise, as much loaded with arms as the inhabitants of the country; a circumstance which told ill for the police of the town, but added considerably to its picturesque effect. Grave men in palanquins, counting their beads, and looking like moullahs, had all two or three sword or buckler lacqueys attending on them. People of more consequence, on their elephants, had each a retinue of shield, spear, and gun, little inferior to that by which we were surrounded; and even the lounging people of the lower ranks, in the streets and shop-doors, had their shields over their shoulders, and their swords carried in one hand." Lucknow is a very ancient city. It was formerly the residence of the governors or nabobs of Oude, but was abandoned by Shujah ad Dowleh after the battle of Buxar; on his death in 1774, however, his successor returned to it; and being now the residence of the kings of Oude, it has been greatly increased, and embellished by palaces and other public buildings; and the bankers and men of property having accompanied the court, Lucknow became one of the largest and richest towns in Hindustan. In advancing into the town, the buildings begin to improve, though the streets continue to be equally narrow and dirty. Some of the streets are, however, more spacious; and one in particular is mentioned as being both wide and handsome. From the dwelling of the British resident, all the way down the principal street, and afterwards through the park of Dil-Koushar and the neighbouring drives, Lucknow appeared to Bishop Heber to have more resemblance to some of the smaller European capitals, such as Dresden, than any other town which he had seen in India. There are several palaces in Lucknow belonging to the king, but none of them are very striking buildings. There is one close to the residency, which is merely a cluster of mean houses, with some morsels of showy architecture intermingled like the offices of a college. The minister's house is a very large pile of buildings, in a dirty part of the town. There are many stately khans, and some handsome mosques and pagodas, scattered in different corners of the most wretched alleys. The most striking buildings in Lucknow are the tombs of the late Nawab Saadut Ali and of the mother of the present king, the gate of Constantinople, and the imumbra or cathedral. The latter building consists of two courts, rising with a steep ascent one above another. It contains, besides a splendid mosque, a college for instruction in Mussulman law; apartments for the religious establishment maintained here; and a noble gallery, in the midst of which, under a brilliant tabernacle of silver, cut glass, and precious stones, lie buried the remains of its founder Asuph ud Dowlah. The whole is in a very noble style of eastern Gothic, and is distinguished by richness and variety, as well as by the just proportions and general good taste of its principal features. Close to this fine group is a large and handsome, though a dull and neglected looking pile, which is the palace or prison appropriated to the unfortunate widows and concubines of deceased sovereigns. There is a small summer palace of the king's about three miles from the city, to which there is a pleasant ride. The house is small and ugly, but the park is extensive, and it is well stocked with Indian deer, and with fine red deer. The king has also a large menagerie, containing a great number of scarce and curious animals; and, on the banks of the river Goomty, in a well wooded park, is a large collection of different varieties of cows, camels, and deer, and five or six very large rhinoceroses. Amongst the curiosities in the neighbourhood is Constantia, the residence of the late General Martin, who, from being a common soldier, rose to a high rank in the Company's army. His house is a large and whimsical building, and the grounds are laid out in the worst possible taste, displaying in the outline and arrangements the eccentric genius of the contriver. To the house is annexed a very fine garden and extensive grounds. The population of Lucknow is estimated at 300,000; and Bishop Heber is of opinion that it is sufficiently crowded to contain that number. There is in Lucknow a considerable number of European inhabitants, consisting of the numerous dependents of the residency, and those Europeans and half castes retained by the king in his employment. There are also many tradesmen amongst both these descriptions of persons, and a strange medley of adventurers of all sects and nations, who ramble thither in search of employment, which, however, they seldom find. It is 650 miles travelling distance from Calcutta, from Delhi 280, from Agra 202, and from Benares 189 miles. Long. 80. 55. E. Lat. 26. 51. N. The district of Lucknow is adjacent to the city, and is situated between the 26th and 27th degrees of N. lat. The country is generally a sandy soil, covered, after a storm, with puddles of water. Some parts, however, are more fertile and better cultivated. The country is watered by the Ganges, the Goggrah, and the Goomty; and over the small river Sye is a bridge of fifteen arches, an excellent specimen of Mahommedan architecture. The towns are mostly built of brick, and there are still in many parts extensive mounds of brick dust, the only vestiges of ancient cities. (Rennell's *Memoir of a Map of Hindustan;* Lord Valentia's *Travels,* &c.)

LUCKPUT BUNDER, a town of Hindustan, province of Cutch, situated about thirty miles up the Lory River or Salt Creek, which communicates with the Gulf of Cutch, and is only navigable for small vessels. It is defended by a fort, which is situated on the brow of a hill. It is not estimated to contain more than 2000 inhabitants, 500 of whom are Sepoys; and it is at present a place of little trade. Lat. 23. 47. N.

LUCRETIA, the famous Roman matron, wife of Collatinus, and the cause of the revolution in Rome by which the constitution of the state was changed from a monarchy to a republic. This lady being ravished by Sextus, the eldest son of Tarquin king of Rome, stabbed herself, in the year 509 before Christ. The bloody poniard, with her dead body exposed to the senate, was the signal of Roman liberty; the expulsion of the Tarquins, and the abolition of the regal dignity, were instantly resolved on, and carried into execution.

LUCRETIUS, T. CARUS, a celebrated Roman poet and philosopher, who was born B. C. 95 and died B. C. 55, according to Donatus (*Vit. Virg.*), or 52 B. C. according to Eusebius. We have no precise information respecting his parents, his education, or the circumstances of his life; and even whether he studied at Athens under Zeno is a matter of considerable doubt. We know, however, that he must have witnessed the proscriptions of Marius and Sylla, and have lived during all the horrors of the civil war, a period full of popular commotions, and crimes of the deepest dye. An ingenious writer has attempted to draw a parallel between those horrible times and the peculiar doctrines which Lucretius advocated. It is said that, not daring to attribute the misery of his country to the justice and wisdom of the gods, he was anxious to dethrone a Providence which seemed to abandon the world to the passions of ambitious tyrants. He borrowed his philosophy from the school of Epicurus, and was evidently well acquainted with the language and manners of the Greeks. His poem entitled *De Rerum Natura* is divided into six books, and addressed to his friend Memmius, one of the most virtuous and enlightened men of his age. There is a tradition that it was composed during the lucid intervals of a madness caused by a love potion which had been administered to him by his wife Lucilia. The talent of Lucretius is displayed by the skilful manner in which he treats his subject, even when its nature is such that it does not admit of poetical embellishment, and by the dignity with which he unfolds his philosophical views. He indulges but seldom in declamation, and every thing is simple and without ornament. The poet has bestowed much care upon the introductory parts of each book, and

Lucullus.

throughout the work there are many beautiful passages and episodes, such as the description of the plague at Athens. The most celebrated passages are the invocation to Venus, the powerful description of love, &c.; but, to form a just idea of his talents, we must read the fifth book, in which he narrates the formation of society. The materials for this work were taken principally from the writings of Epicurus. In the design he seems to imitate the unadorned and almost prosaic poetry of Empedocles. The language, rich in antique forms and expressions, is thus full of power and energy; but that he had many difficulties with which to contend, is proved by his complaints of the poverty of the Latin language, and by the introduction of many Greek words, which are seldom to be met with in other Roman authors. His philosophy is that of the atheist; he denies the existence of a Deity and of a Providence; he disbelieves the immortality of the soul, and laughs at the idea of death. From the depths of this heartless scepticism, however, he darts at times to the very heights of enthusiasm and poetry. But the character of his system experiences no change. He destroys all those gods with whom the poets loved to people the universe; he ridicules the idea of a future life, and of future rewards and punishments; he represses all hopes, and stifles all fear; yet all ages have admired this poem of Lucretius, as one of the most wonderful productions of human genius. It is said by Eusebius that Cicero revised and published this work, and yet it is remarkable that he only mentions Lucretius once, and then his praise is but equivocal (Cic. *ad Q. Fratr.* ii. 2). Ovid promises immortality to his verses.

Carmina sublimis tunc sunt peritura Lucreti,
Exitio terris cum dabit una dies.

There have been many editions of this work. The first edition known is in folio, without date, and appears to be that of Thomas Ferrand, printed at Brescia in 1473. The others are, Veron. 1486; Venetiis apud Aldum, 1500; cum comment. Lambini, Paris, 1564, 1570; cum notis Creech, Oxon. 1695; ed. Wakefield, Lond. 1796; ed. Eichstædt, Lips. 1801; ed. Forbiger, Lips. 1828.

LUCULLUS, Lucius Licinius, a Roman general celebrated for his eloquence, his victories, and his riches. In his youth he made a figure at the bar; but being afterwards sent as quæstor into Asia, and prætor into Africa, he governed those provinces with great moderation and justice. Scarcely was he known as a military man, when he twice defeated the fleet of Hamilcar, and gained two great victories over him. His happy genius was greatly improved by study; for he employed his leisure in reading the best authors on military affairs. Being made consul along with Aurelius Cotta, during the third war with Mithridates king of Pontus, he was sent against that prince; and this expedition was attended with a series of victories, which did him less honour than an act of generosity towards his colleague. The latter, willing to take advantage of his absence to signalize himself by some great exploit, hastened to fight Mithridates, but was defeated and shut up in Chalcedonia, where he must have perished, if Lucullus, sacrificing his resentment to the pleasure of saving a Roman citizen, had not flown to his assistance, and disengaged him. All Pontus then submitted to Lucullus, who being continued in his government of Asia, entered the territories of Tigranes, then the most powerful king in Asia. That prince marched with a formidable army against Lucullus, who defeated him with a handful of men, and killed great numbers of his forces; took Tigranocertes, the capital of his kingdom; and was ready to put an end to the war, when the intrigues of a tribune got him deposed, and Pompey nominated in his stead. Lucullus having brought home prodigious riches, now gave himself up to excessive luxury; and his table was served with a profusion and splendour until that time unknown. He brought from the East a great number of books, which he formed into a library, and gave admission to all men of learning, who frequented it in great numbers. Towards the end of his life, he fell into a kind of madness; and Lucullus, his brother, was appointed his guardian. He is said to have been the first who brought cherries into Europe, having imported the grafts from the kingdom of Pontus.

Lucus
Ludius.

LUCUS, in general, denotes a wood or grove sacred to a deity; so called *a lucendo*, because a great number of lights were usually kept burning in honour of the god, a practice common with idolaters, as we learn from Scripture.

LUD, a British king mentioned in our old chronicles, and said to have reigned about the year of the world 3878. He is reported to have enlarged and walled round *Troynovant*, or New Troy, where he kept his court, and made it his capital. The name of London is derived from *Lud's town*, and Ludgate from his being buried near it; but this is only one amongst many other derivations of the name of London, which are at least equally probable.

LUDAMAR, a country of Central Africa, situated in latitude 16. 30. north, and longitude 6. 30. west, and bounded on the south by Kaarta and Bambara, on the east by Timbuctoo, and on the north by the Great Desert. The inhabitants are Moors, who live in a state of great barbarity and bigoted Mahommedanism. They entirely neglect agriculture, and depend chiefly for subsistence on the rearing of cattle. Their only knowledge of manufactures consists in converting iron into spears and knives, and weaving cloth from goats' hair. Almost every inhabitant capable of bearing arms is liable to be called out in a military capacity, and must furnish his own horse and equipments. The king administers justice, but seldom inflicts capital punishments. He is distinguished from his subjects only by his dress being of a finer cloth, and by a tent of larger dimensions; but in ordinary intercourse his rank is little attended to; and he often eats out of the same dish, and sleeps in the same bed, with his menials. It was in this country that the traveller Major Houghton met his death, and Mr Park suffered such a rigorous captivity. The chief town is Benown, a miserable place, consisting of a number of dirty-looking huts scattered irregularly over an extensive space, and resembling a camp rather than a town.

LUDEHAUNAH, a town of Hindustan, situated on the north-west boundary of the province of Delhi, and on the south bank of the Sutlege river. It is one of the most remote military stations which the British possess in this quarter. The climate is cold for four months of the year, and in the summer season extremely hot, with hot winds. The rains are abundant. It is 180 miles north-north-west from the city of Delhi, and 120 south-east from Lahore. Long. 75. 32. E. Lat. 36. 53. N.

LUDENSCHEID, a city of the Prussian government of Arensburg, in Westphalia, in the circle of Altena. It stands between two lofty hills, and contains a Lutheran and a Calvinist church, 280 houses, and 1820 inhabitants. It is a place celebrated for its hardware, especially for saws, scythes, hoops, and many other articles.

LUDGERSHALL, a market and borough town of the county of Wilts, in the hundred of Amesbury, seventy miles from London and fifteen from Salisbury. It is pleasantly situated on the borders of the forest of Chute. It formerly returned two members to the House of Commons, but has been deprived of that privilege by the reform act. The population amounted in 1801 to 471, in 1811 to 487, in 1821 to 477, and in 1831 to 535.

LUDI, a term used for shows and public representations exhibited by the Romans for the entertainment of the people.

LUDIUS, a celebrated painter, who lived in the reign of Augustus Cæsar, and excelled in grand compositions. He was the first who painted the fronts of houses in the streets of Rome, which he beautified with a great variety of landscapes and many other subjects.

LUDLOW, Edmund, son of Sir Henry Ludlow, was born at Maidenhead, and educated in Trinity College, Oxford. His father being opposed to the king's interest, Mr Ludlow joined the same party, and was present at the battle of Edgehill as a volunteer under the Earl of Essex. Upon the death of his father, he was chosen knight of the shire for Wilts, and obtained the command of a regiment of horse for the defence of that county. He was one of the judges of Charles I. and after his death was sent by the parliament into Ireland, in quality of lieutenant-general of the horse, an employment which he discharged with diligence and success until the death of the lord-deputy Ireton, when he acted for some time as general, though without that title; Cromwell, who knew him to be sincerely in the interest of the commonwealth, always finding out some pretext to evade conferring that office upon him. The last stroke would have been given by Ludlow to the Irish rebellion, if the usurpation of Cromwell had not prevented it. Under his power he never acted; and though Cromwell used his utmost efforts to gain him, he remained inflexible. After Cromwell's death, he endeavoured to restore the commonwealth; but Charles II. being recalled, he thought proper to conceal himself, and escaped into Switzerland, where he settled. After the revolution, he came over to England, in order to be employed in Ireland against King James; but having appeared publicly in London, it gave great offence, and an address was presented by Sir Edward Seymour to King William III. praying for a proclamation in order to apprehend Colonel Ludlow, attainted for the murder of King Charles I. Upon this he returned to Switzerland, where he died. During his retirement in that country he wrote his Memoirs.

Ludlow, a borough and market town of the county of Salop, in the hundred of Munslow, 142 miles from London. It is situated at the confluence of the rivers Teme and Corfe, is well built, paved, and lighted, and has a spacious town-hall, a neat hospital, and school-house. The ancient castle, now in a state of dilapidation, was formerly used by the president of the court of the marches of Wales, and has been immortalized as the theatre of the first display of the poetic powers of Milton. The corporation consists of a high bailiff, two justices, twelve aldermen, and twenty-four common-council men. It is represented by two members in the House of Commons. The quarter-sessions for the county are held here, as well as a court of record for the borough. There are annual races, which are much attended. Ludlow is a cheap place, and has good markets on Monday, Wednesday, and Friday. The inhabitants amounted in 1801 to 3897, in 1811 to 4150, in 1821 to 4820, and in 1831 to 5253.

LUDOLPH, Job, a learned writer of the seventeenth century, was born at Erfurt, in Thuringia. He travelled much, was master of twenty-six languages, visited libraries, searched everywhere after natural curiosities and antiquities, and conversed with learned men of all nations. He published a History of Ethiopia, and other curious books.

Ludolph, *Henry William*, nephew of Job above mentioned, was born at Erfurt in 1655. He came to England as secretary to M. Lenthe, envoy from the court of Copenhagen to that of London; and being recommended to Prince George of Denmark, he was received by that prince as his secretary. He enjoyed this office for some years, until he was incapacitated by a violent disorder, when he was discharged with a handsome pension. After he had recovered, he travelled into Muscovy, where he was well received by the czar, and where his knowledge led the ignorant Muscovite priests to believe him a conjuror. On his return to London in 1694, he was cut for the stone; and, as soon as his health would permit, in acknowledgment of the civilities he received in Muscovy, he wrote a grammar of their language, that the natives might learn their own tongue in a regular method. He then travelled into the East, to inform himself of the state of the Christian church in the Levant; the deplorable condition of which induced him, after his return, with the aid of the Bishop of Worcester, to print an edition of the New Testament in the vulgar Greek, in order to present it to the Greek church. In 1709, when such numbers of Palatines came over to England, Mr Ludolph was appointed by Queen Anne one of the commissioners to manage the charities raised for them; and he died early in the following year. His collected works were published in 1712.

LUDWIGSBURG, a city of the kingdom of Wirtemburg, in the circle of the Neckar, and the capital of a bailiwick of the same name. It is situated in a rich and beautiful district, one of the royal residences, and the seat of the financial boards of the kingdom, is well built, and contains 1000 houses, with 5426 inhabitants, a considerable garrison, and a military academy. It has manufactures of cotton, woollen, and china-ware. The promenades around it are pleasant, and near to it is the palace Monrepos, the residence of the late dowager queen, formerly princess royal of England. Long. 9. 1. 32. E. Lat. 48. 53. 15. N.

LUDWIGSLUST, a town of the grand duchy of Mecklenburg-Schwerin, in the bailiwick of Grabow. It is the residence of the sovereign, who has a fine palace, with parks and pleasure-gardens around it. The palace is a large and highly-ornamented building, and contains a picture-gallery with some fine paintings. A new road, recently constructed, connecting Berlin with Hamburg, passes through this place, by which means it has become a great thoroughfare. The town contains a Lutheran and a Catholic church, 624 houses, and 3840 inhabitants, mostly depending for subsistence on the court.

LUFF, the order from the pilot to the steersman to put helm towards the lee-side of the ship, in order to make the ship sail nearer the direction of the wind. Hence, luff round, or luff a-lee, is the excess of this movement, by which it is intended to throw the ship's head up in the wind in order to tack her. A ship is also said to spring her luff when she yields to the effort of the helm, by sailing nearer to the line of the wind than she had done before.

Luff Tackle, a name given by sailors to any large tackle that is not destined for a particular place, but may be variously employed as occasion requires. It is generally somewhat larger than the jigger tackle, although smaller than those which serve to hoist the heavier materials into and out of the vessel, which latter are the main and fore tackles, the stay and quarter tackles, and so forth.

LUG-SAIL, a square sail, hoisted occasionally on the mast of a boat or small vessel, upon a yard which hangs nearly at right angles with the mast. These sails are more particularly used in the barca-longas navigated by the Spaniards in the Mediterranean.

LUGANO, a city, the capital of a circle of the same name, in the canton of Ticino, in Switzerland. It stands in a romantic situation on the lake of its own name, famous for the quantity and excellence of the fish caught in it, which in some degree supply Milan with that species of food. It is well built, and contains sixteen churches, seven religious houses, an ecclesiastical seminary, and 398 houses, with 4350 inhabitants, who are actively employed in the manufactures of silk, paper, and ironware, and grow abundance of moderately good wine. Long. 8. 57. 35. E. Lat. 45. 59.

56. N. It is the capital of the canton alternately with Belling and Locarno.

LUGDUNUM, in *Ancient Geography*, the capital of the Segusiani, in Gallia Celtica, situated on an eminence at the conflux of the Arar and Rhodanus, as the Celtic term *dun* indicates. It was built by Manutius Plancus, under Augustus, while commanding in that part of Gaul, and thither he led a colony. Lugdunum is now *Lyons*, capital of the Lyonnois.

Lugdunum Batavorum, in *Ancient Geography*, a town of the Batavi, in Gallia Belgica; now *Leyden*, in Holland.

LUGO, a city of Spain, in the province of Galicia, on the river Tuy, which runs to the Mino. In this place there are some manufactories of linen and stockings, and some tanneries. Near it is the mountain village of Cerbrero, whose fields are covered with snow four months in the year, but whose pasture in summer is excellent, and produces cheese, which is highly esteemed throughout Spain. At this place the army under Sir John Moore, in his celebrated retreat, having suffered the greatest hardships from the severity of the climate, the haste of their march, and the want of the requisite refreshments, offered battle to the enemy, which, however, was declined.

LUGOS, a town of the circle of Temesvar, in the province of Farther Theiss, in Hungary. It stands on the river Temes. It is the place of assembly of the provincial states, has a Minorite monastery and a Greek church, and contains 900 houses, with 4587 inhabitants, who grow some excellent wine. Long. 21. 52. 30. E. Lat. 45. 37. 50. N.

LUKE, St, the evangelist, and disciple of the apostles, was originally of Antioch, in Syria, and by profession a physician. He particularly attached himself to St Paul, and was his faithful companion in his travels and labours. He went with the apostle to Troas, in Macedonia, about the year 51; he wrote his gospel in Achaia about the year 53; and, ten years after, he compiled the Acts of the Apostles, which contains a history of thirty years. Of all the inspired writers of the New Testament, his works are written in the most elegant Greek. It is believed that St Luke died at Rome, or in Achaia.

Gospel of St Luke, a canonical book of the New Testament. Some think that it was properly St Paul's Gospel; and that, when the apostle speaks of *his* gospel, he means what is called St Luke's. Irenæus says that St Luke digested into writing what St Paul preached to the Gentiles; and Gregory Nazianzen tells us that St Luke wrote with the assistance of St Paul.

St Luke the Evangelist's Day, a festival in the Christian Church, observed on the 18th of October.

LUKIANOW, a circle of the province of Nishegorod, in Russia, extending from latitude 54. 31. to 54. 14. and from longitude 43. 43. to 45. 28. east. It is well supplied with the means of conveyance, by several rivers running into the Wolga, for its chief products, which consist of rye, hemp, and flax. It contains 185,000 inhabitants, of whom 50,000 are slaves. The capital, a city of the same name, is 840 miles from St Petersburg, at the junction of the rivers Tescha and Kochschtschwaki, and contains 267 houses, with 1560 inhabitants. Long. 44. 20. E. Lat. 55. 54. N.

LULLI, Jean Baptiste, one of the most celebrated musicians that has appeared in France since the revival of learning, was born at Florence. He was taken to France when very young, by a person of quality; and he carried the art of playing on the violin to the highest perfection. Louis XIV. appointed him superintendent of music. Some time afterwards, Perinna having introduced operas into France, and quarrelled with his company, he resigned his privilege to Lulli. Operas were then carried to the utmost perfection by this celebrated musician, and were attended with continual applause. From this time, Lulli every year produced a piece of his own composition, until his death, which happened in the year 1687.

LULLY, Raymond, a writer on alchemy, surnamed the Enlightened Doctor, was born in the island of Majorca in 1225. He applied himself with indefatigable labour to the study of the Arabian philosophy, chemistry, physic, and divinity, and acquired great reputation by his works. He at length went to preach the gospel in Africa, and was stoned to death in Mauritania, at the age of eighty. He is honoured as a martyr at Majorca, whither his body was carried. He wrote many treatises on the sciences, in which he shows much study and subtilty, but little judgment or solidity. A complete edition of his works was printed at Mentz. This person must not be confounded with Raymond Lully of Terraca, surnamed *Neophyta*, who, from being a Jew, turned Dominican friar, and maintained several opinions which were condemned by Gregory XI.

LUMGHANAT, an Afghan district in the province of Cabul, and situated principally on the banks of the Kameh River, but which formerly extended from the Indus to the Hindoo Koosh Mountains. The chief towns are, Jellalabad and Irjah. It was formerly a Hindu territory, and the natives had a peculiar dialect; but it is now possessed by different tribes of Afghans, particularly the Hazarehs.

LUMINOUS, an epithet applied to any thing that shines or emits light.

Luminous Emanations have been observed from human bodies, as also from those of brutes. The light arising from currying a horse, or from rubbing a cat's back, are well known. Instances of a similar kind have been observed on combing a woman's head. Bartholin gives us an account, which he entitles *Mulier Splendens*, of a lady in Italy whose body shone whenever slightly touched with a piece of linen. These effluvia of animal bodies have many properties in common with those produced from glass; such as being lucid, snapping, and not being excited without some degree of friction; and they are undoubtedly electrical, as a cat's back when stroaked has been found strongly electrical.

LUMEZZANO, two towns of Italy, in the delegation of Brescia, part of the Austrian government of Milan. One of them, with the addition of St Apollonia, is situated on a hill, and contains 1386 inhabitants; the other, called De Pieve, is situated in the valley of Trompia, and contains 1310 inhabitants. Both are celebrated for their manufactures of bayonets, gun-stocks, muskets, swords, pistols, daggers, and other weapons.

LUNA, in the jargon of the alchemists, signifies *silver*, which was so called from the supposed influence of the moon upon that metal.

Luna Cornea, in *Chemistry*, is a compound of muriatic acid with silver.

LUNAR, something relating to the moon.

Lunar Month. See Month.

Lunar Year consists of 354 days, or twelve synodical months. See Calendar and Year.

LUNAWARA, a town of Hindustan, in the province of Gujerat, and district of Gudara, where, in 1803, a treaty was concluded with the rajah by the British government, which freed him from the tribute he had before paid to Scindia. Long. 73. 46. E. Lat. 23. 5. N. It is sixty-five miles east-north-east from Ahmedabad.

LUND, a city of Sweden, in the province of Malmoe, near the river Hoje-An. It is without walls, and is the seat of a bishop, of a theological seminary, and of a university. There is a respectable cathedral, besides three other churches; and it contains about 400 houses, with 3640 inhabitants. The university has great reputation, and appropriate institutions to assist study. The library consists of 40,000 volumes, and there are good collections of natual history, of mechanical models, an observatory with good astronomical instruments, and a well-arranged botanical garden. The students at the full session are about [illegible]0. There are some manufactures, but the chief trade is that which arises from the university. Long. 13. 7. 22. E. Lat. 55. 42. 26. N.

LUNDY, an island in the mouth of the Bristol Channel, about eleven miles from the coast of Devonshire. It is about five miles in length and two in breadth, and is surrounded by rocks, except at one part, which is so narrow as to admit of not more than one person at a time reaching it. It has living on it but one family, who breed pigs, goats, and rabbits, and supply fowls and eggs to a part of the towns in Devonshire. Long. 4. 9. W. Lat. 51. 20. N.

LUNE, Lunula, in *Geometry*, a plane in the form of a crescent or half-moon, terminated by the circumference of two circles, which intersect each other within.

LUNEBURG, one of the provinces of the present kingdom of Hanover. It was formerly the duchy of that name, erected by the emperor of Germany, in the year 1235, and at length came to the Hanoverian branch of the family of Brunswick. It extends along the left bank of the river Elbe, by which it is divided from the Prussián and the Danish dominions. It is 4475 square miles in extent, and comprehends twelve cities, twenty-six market-towns, 184 parishes, in which are 1501 hamlets, 32,944 houses, and about 280,000 inhabitants. It is generally a level district, with a sandy soil; but near the rivers there is some good arable and pasture land, though the heaths form seven tenths of the whole province. The principal river is the Elbe, into which the Ilmenau, the Ohre, and their tributary streams, fall; but some of the rivers run to the Weser. The climate, though not unhealthy, is severely cold in winter, and as intensely hot in summer. The chief employment, besides husbandry, is spinning flax. The capital is the city of the same name, on the Ilmenau, which is navigable to the Elbe. It contains four churches, an orphan-house, two hospitals, and 1898 dwellings, mostly in a very ancient style, and 10,039 inhabitants. The place is now in a dilapidated state, and there are few public buildings, though there are institutions for education. There is but little trade, except in salt made from a saline spring, and in brewing, distilling, and tanning, for the use of the neighbourhood. Long. 10. 19. 32. E. Lat. 53. 15. 7. N.

LUNEL la Bille, a city of France, in the department of the Hérault and arrondissement of Montpellier. It is situated on a canal, connecting the river Bedairie with the lake of Magicio. It contains 650 houses, and 45,000 inhabitants, who produce Muscatel wine of a very celebrated flavour. Long. 4. 3. E. Lat. 43. 38. N.

LUNEVILLE, an arrondissement of the department of the Meurthe, in France. It extends over 672 square miles, is divided into seven cantons and 209 communes, and contains 71,500 inhabitants. The capital is the city of the same name, at the influx of the Bézouse into the Meurthe. The situation is very fine, and the country around it fertile. It is celebrated for the peace between Austria and France, which was concluded there in 1801. It contains 1300 houses, and 11,600 inhabitants. Long. 6. 5. 1. E. Lat. 48. 35. 33. N.

LUNENSE Marmor, in the natural history of the ancients, the name of that species of white marble now known amongst us by the name of *Carrara marble*, and distinguished from the statuary kind by its greater hardness and inferior splendour. It has ever been greatly esteemed in building and ornamental works, and is so still. It is of a close and fine texture, of a pure white, and much more transparent than any other of the white marbles. It has always been found in great quantities in Italy, and is so to this day.

LUNETTE, in *Fortification*, an enveloped counterguard, or elevation of earth, made beyond the second ditch, opposite to the places of arms, and differing from the ravelins only in situation. *Lunettes* are usually made in ditches full of water, and serve the same purpose as faussebrayes, namely, to dispute the passage of the ditch. *Lunettons* are small lunettes.

Lunette, in the manège, is a half horse-shoe, or such a shoe as wants the sponge, that is, the part of the branch which runs towards the quarters of the foot.

Lunette is also the name of two small pieces of felt, made round and hollow, to clap upon the eyes of a vicious horse, that is apt to bite, and strike with his fore feet, or that will not suffer his rider to mount.

LUNGS. See Anatomy.

LUNISOLAR Year, in *Chronology*, the space of 532 common years; found by multiplying the cycle of the sun by that of the moon.

LUPERCALIA, feasts instituted in ancient Rome, in honour of the god Pan. The word comes from *Lupercal*, the name of a place under the Palatine Mount, where the sacrifices were performed. The Lupercalia were celebrated on the 15th of the kalends of March, that is, on the 15th of February, or, as Ovid observes, on the 3d day after the ides. They are supposed to have been established by Evander. On the morning of this feast, the Luperci, or priests of Pan, ran naked through the streets of Rome, striking the married women they met on the hands and belly with a thong or strap of goats' leather, which was held an omen promising them fecundity and happy deliveries. This feast was abolished in the time of Augustus; but afterwards restored, and continued to the time of the Emperor Anastasius. Baronius says it was abolished by the pope in 496.

LUPERCI, a name given to the priests of the god Pan. The *luperci* were the most ancient order of priests in Rome; they were divided into two colleges or companies, the one called *Fabii* and the other *Quintilii*. To these Cæsar added a third, which he called *Julii*.

LURCHER, a kind of hunting-dog, much like a mongrel greyhound, with pricked ears, a shagged coat, and generally of a yellowish-white colour.

LURE, in falconry, a device of leather, in the shape of two wings, stuck with feathers, and baited with a piece of flesh, to call back a hawk when at a considerable distance

Lure, an arrondissement of the department of the Upper Saone, in France, extending over 881 square miles. It is divided into ten cantons, and these again into 211 communes, containing 118,500 inhabitants. The capital is the city of the same name, situated on the river Oignon, in a district woody and mountainous, in which are numerous mines of coal. It contains 430 houses, and 2420 inhabitants.

LURGAN, a town in the county of Armagh and province of Ulster, in Ireland, sixty-six miles from Dublin. It is a flourishing town, agreeably situated in the midst of a much improved country; and the inhabitants are extensively engaged in the linen manufacture. It stands on a gentle eminence, about two miles from Lough Neagh, of which it commands a most beautiful and extensive prospect. Long. 6. 31. W. Lat. 54. 35. N.

Lurgan Green, a town of Ireland, in the county of Louth and province of Leinster, thirty-seven miles from Dublin; a little beyond which is a handsome seat of the Earl of Charlemont.

LUS, a city of France, the capital of a canton in the department of the Upper Pyrenees. It stands in a romantic situation in the pleasing valley of Bastan, at the foot of the Pic de Leyrey, and on the Gave de Barrèges, and contains about 2200 inhabitants. Near to it is the mineral spring of St Sauveur, which is frequented by invalids, both for drinking and bathing, the water being of the temperature 98° of Fahrenheit.

Lus, a district in the eastern part of the Persian province of Mekran, the country of the ancient Oritæ. It is of a circular form, and bounded on three sides by an immense range of mountains, separating it from the western part of Mekran, Beloochistan, and Scind. The face of the country is flat and sandy, producing abundant crops of every species of grain. There are four passes through the mountains which encompass Lus; two into Scind, one into western Mekran, and one into Beloochistan. The country is under the jurisdiction of a petty chief, who can bring about 4000 irregular troops into the field, and enjoys a revenue of 50,000 rupees per annum. The capital is Bayla; but the chief maritime port is Sommeany, which is a small and mean place.

LUSATIA. See Lausatia.

LUSITANIA, in *Ancient Geography*, one of the divisions of Spain, extending to the north of the Tagus, quite to the sea of Cantabria, at least to the Promontorium Celticum. But Augustus, by a new regulation, made the Anas its boundary to the south, and the Durius to the north; thus constituting only a part of the modern Portugal.

LUSTRAL, an epithet given by the ancients to the water used in their ceremonies for sprinkling and purifying the people. From them the Catholics have borrowed the holy water used in their churches.

Lustral Day (*Dies Lustricus*), that on which the lustrations were performed for a child, and its name given, which was usually the ninth day after the birth of a boy, and the eighth after that of a girl; though some performed the ceremony on the last day of the week in which the child was born, and others on the fifth day after its birth.

Over this feast-day the goddess Nundina was supposed to preside. The midwives, nurses, and domestics handed the child backwards and forwards, around a fire burning on the altars of the gods, after which they sprinkled it with water; and hence this feast received the name of *amphidromia*. The old women mixed saliva and dust with the water; and the whole ended with a sumptuous entertainment. The parents received gifts from their friends on this occasion. If the child was a male, their door was decked with an olive garland; if a female, with wool, denoting the work about which women were employed.

LUSTRATION, in *Antiquity*, sacrifices or ceremonies by which the ancients purified their cities, fields, armies, or people, defiled by any crime or impurity. Some of these lustrations were public and others private. There were several ways of performing lustration, viz. by fire, by sulphur, by water, and by air, the last being done by fanning and agitating the air round the thing to be purified. Some of these lustrations were necessary, and could not be dispensed with, as lustrations of houses in time of a plague, or upon the death of any person; others, again, were performed from choice, and at pleasure. The public lustrations at Rome were celebrated every fifth year, in which they led a victim thrice round the place to be purified, and in the mean time burned a great quantity of perfumes. The country lustrations, called *ambarvalia*, were celebrated before the peasants began to reap the corn; in those of the armies, called *armilustria*, some chosen soldiers, crowned with laurel, led the victims, a cow, a sheep, and a bull, thrice round the army ranged in battle-array in the field of Mars, to which deity the victims were subsequently sacrificed, after pouring out many imprecations upon the enemies of the Romans. The lustrations of the flocks were performed in this manner. The shepherd sprinkled them with pure water, thrice surrounded his sheepfold with a composition of savin, laurel, and brimstone set on fire, and afterwards sacrificed to the goddess Pales an offering of milk boiled, wine, a cake, and millet. As for private houses, they were lustrated with water, a fumigation of laurel, juniper, olive-tree, savin, and the like; and the victim was commonly a pig. Lustrations made for particular persons were commonly called *expiations*, and the victims *piacula*. There was also for infants a kind of lustration, by which they were purified, girls on the third, and boys on the ninth day after their birth; a ceremony which was performed with pure water and spittle. In lustratory sacrifices, the Athenians sacrificed two men, one for the men of their city, and the other for the women. Several of these expiations were austere; some fasted, others abstained from all sensual pleasures; and a few, as the priests of Cybele, castrated themselves. The postures of the penitents were different according to the different sacrifices. The priests changed their habits according to the ceremony to be performed; but white, purple, and black, were the most usual colours. They cast into the river, or at least out of the city, the animals or other things which had served for a lustration or sacrifice of atonement; and thought themselves threatened with some great misfortune when by chance they trod upon them. Part of these ceremonies were abolished by the Emperor Constantine and his successors; the rest subsisted till the Gothic kings became masters of Rome, when they expired.

LUSTRUM, in Roman antiquity, a general muster and review of all the citizens and their goods, which was performed every fifth year by the censors, who afterwards made a solemn lustration. This custom was first instituted by Servius Tullius, about 180 years after the foundation of Rome. In the course of time the lustra were not celebrated so often; for we find the fifth lustrum celebrated at Rome only in the 574th year of that city.

LUTE, or Loting, amongst chemists, a mixed, tenacious, ductile substance, which grows solid by drying, and, being applied to the juncture of vessels, stops them up so as to prevent the air from getting in or out.

Lute is also a stringed musical instrument. The lute consists of four parts; the table; the body or belly, which has nine or ten sides; the neck, which has nine or ten stops or divisions, marked with strings; and the head or cross, where the screws for raising and lowering the strings to a proper pitch of tone are fixed. In the middle of the table there is a rose or passage for the sound; there is also a bridge to which the strings are fastened, and a piece of ivory between the head and the neck to which the other extremities of the strings are fitted. In playing, the strings are struck with the right hand, and with the left the stops are pressed. The lutes of Bologna are esteemed the best, on account of the wood, which is said to be peculiarly fitted for producing a sweet sound.

LUTETIA Parisiorum, in *Ancient Geography*, a town of the Parisii, in Gallia Celtica, situated on an island in the Sequana or Seine. It received its name, as some suppose, from the quantity of clay, *lutum*, which is found in its neighbourhood. Julius Cæsar fortified and embellished it, from which circumstance some authors call it *Julii Civitas*. Julian the Apostate resided there for some time. It is now *Paris*, the capital of France, being so called from its name *Paryis* in the lower age.

LUTHER, Martin, the famous author of the Reformation, was a native of Eisleben, in Saxony, and born in 1483. Though his parents were poor, he received a learned education, during the progress of which, he gave many indications of uncommon vigour and acuteness of genius. As his mind was naturally susceptible of serious impressions, and somewhat tinctured with that religious melancholy which delights in the solitude and devotion of a monastic life, he retired into a convent of Augustinian friars, where he acquired great reputation, not only for piety, but also for love of knowledge and unwearied application to study. The cause of this retirement is said to have been, that he was once struck by lightning, whilst his companion was killed by his side by the same flash. He had been taught the scholastic philosophy which was in vogue in those days, and had made considerable progress in it; but hap-pening to find a copy of the Bible which lay neglected in the library of his monastery, he applied himself to the study of it with an eagerness and assiduity which quite astonished the monks, and so much increased his reputation for sanctity, that he was chosen professor, first of philoso-phy, and afterwards of theology, at Wittemberg, on the Elbe, where Frederick elector of Saxony had founded an university.

Whilst Luther continued to enjoy the highest reputation for sanctity and learning, Tetzel, a Dominican friar, came o Wittemberg in order to publish indulgences. Luther beheld his success with great concern; and having first nveighed against indulgences from the pulpit, he after-wards published ninety-five theses, containing his senti-ments on that subject. These he proposed, not as points fully established, but as subjects of inquiry and disputation. He appointed a day on which the learned were invited to mpugn them either in person or by writing; and to the whole he subjoined solemn protestations of his high respect for the apostolic see, and of his implicit submission to its authority. No opponent appeared at the time fixed; but he theses spread over Germany with astonishing rapidity, nd were read with the greatest eagerness.

Though Luther met with no opposition for some little me after he began to publish his new doctrines, it was not ong before many zealous champions arose to defend those pinions with which the wealth and power of the clergy were so strictly connected. Their cause, however, was by no means promoted by these endeavours; for the people began o call in question even the authority of the canon law, and f the pope himself. The court of Rome at first despised hese new doctrines and disputes; but at length the atten-on of the pope being excited by the great success of the eformer, and the complaints of his adversaries, Luther was, n the month of July 1518, summoned to appear at Rome, within sixty days, before the auditor of the chamber; and ne of his adversaries, named Prierias, who had written gainst him, was appointed to examine his doctrines, and o decide concerning them. At the same time the pope wrote to the elector of Saxony, beseeching him not to pro-ect a man whose heretical and profane tenets were so hocking to pious ears; and enjoined the provincial of the Augustinians to check by his authority the rashness of an rrogant monk, which brought disgrace upon their order, nd gave offence and disturbance to the whole church.

From these letters, and the appointment of his open nemy Prierias as his judge, Luther easily foresaw what ntence he might expect at Rome; and therefore dis-overed the utmost solicitude to have his cause tried in ermany, and before a less suspected tribunal. He wrote submissive letter to the pope, in which he promised an nreserved obedience to his will, for as yet he entertained o doubt of the divine origin of the papal authority; and y the intercession of the other professors, Cajetan, the ope's legate in Germany, was appointed to hear and de-rmine the cause. Luther appeared before him without esitation; but Cajetan thought it below his dignity to dis-ute the point with a person so much his inferior in rank, nd therefore required him, by virtue of the apostolic powers ith which he was invested, to retract the errors which he ad uttered with regard to indulgences and the nature of ith, and to abstain for the future from the publication of ew and dangerous opinions, at the same time forbidding m to appear in his presence, unless he proposed to com-y with what had been required of him.

This haughty and summary manner of proceeding, together with some other circumstances, gave Luther's friends strong reason to suspect that even the imperial safe-conduct would not be sufficient to protect him from the legate's power and resentment; and they prevailed on him secretly to withdraw from Augsburg, where he had attended the legate, and to return to his own country. But before his departure, he prepared, according to a form of which there had been some examples, a solemn appeal from the pope ill informed concerning his cause, to the pope when he should receive more full information with respect to it. Cajetan, enraged at Luther's abrupt retreat, and at the publication of his appeal, wrote to the elector of Saxony, complaining of both, and requiring him, as he regarded the peace of the church, or the authority of its head, either to send the seditious monk as a prisoner to Rome, or to banish him out of his territories. The elector had hitherto, from political motives, protected Luther, thinking he might be useful in checking the enormous power of the see of Rome; and though all Germany resounded with his fame, the elector had never yet admitted him into his presence. But upon this demand being made by the cardinal, it became necessary to throw off somewhat of his former reserve. He had been at great expense, and bestowed much attention, on founding a new university, an object of considerable importance to every German prince; and foreseeing how fatal a blow the removal of Luther would be to its reputation, he not only declined complying with either of the pope's requests, but openly discovered great concern for Luther's personal safety.

In the mean time, the situation of the reformer became daily more and more embarrassing. He knew very well what were the motives which induced the elector to afford him protection, and that he could by no means depend upon a continuance of his friendship. If he should be obliged to quit Saxony, he had no other asylum, and would stand exposed to whatever punishment the rage or bigotry of his enemies could inflict; and so ready were his adversaries to condemn him, that he had been declared a heretic at Rome before the expiration of the sixty days allowed him in the citation for making his appearance. Notwithstanding all this, however, he discovered no symptoms of timidity or remissness, but continued to vindicate his own conduct and opinions, and to inveigh against those of his adversaries with greater vehemence than ever. Being convinced, therefore, that the pope would soon proceed to the most violent measures against him, he appealed to a general council, which he affirmed to be the representative of the Catholic church, and superior in power to the pope, who, being a fallible man, might err, as St Peter, the most perfect of his predecessors, had done.

The court of Rome were in the mean time equally assiduous to crush the author of these new doctrines, which gave them so much uneasiness. A bull was issued by the pope, of a date prior to Luther's appeal, in which he magnified the virtues of indulgences, and subjected to the heaviest ecclesiastical censures all who presumed to teach a contrary doctrine. Such a clear decision of the sovereign pontiff against him might have been fatal to the cause of Luther, had not the death of the Emperor Maximilian, which happened on the 17th of January 1519, contributed to give matters a different turn. Both the principles and interest of Maximilian had prompted him to support the authority of the see of Rome; but, in consequence of his death, the vicariate of that part of Germany which is governed by the Saxon laws devolved to the elector of Saxony; and, under the shelter of his friendly administration, Luther himself enjoyed tranquillity, and his opinions took such root in different places, that they could never afterwards be eradicated. At the same time, as the election of an emperor was a point more interesting to the pope, Leo X., than a theological controversy which he did not understand, and of which he could not foresee the consequences, he was so extremely solicitous not to irritate a prince of such considerable influence in the electoral college as Frederick, that he discovered a great unwillingness to pronounce the sentence of excommunication against Luther, which his adversaries continually demanded with the most clamorous importunity.

From the reason just now assigned, and Leo's natural aversion to severe measures, a suspension of proceedings against Luther ensued for eighteen months, though perpetual negociations were carried on during this interval in order to bring the matter to an amicable issue. The manner in which these were conducted having given our reformer many opportunities of observing the corruption of the court of Rome, its obstinacy in adhering to established errors, and its indifference about truth, however clearly proposed or strongly proved, he began, in 1520, to utter some doubts with regard to the divine origin of the papal authority, which he publicly disputed with Eccius, one of his most learned and formidable antagonists. The dispute was indecisive, both parties claiming the victory; but it must have been very mortifying to the partizans of the Catholic church to hear such an essential point of their doctrine publicly attacked.

The papal authority being once suspected, Luther proceeded to push on his inquiries from one doctrine to another, until at last he began to attack the firmest foundations on which the wealth and power of the church were established. Leo then began to perceive that there were no hopes of reclaiming such an incorrigible heretic, and therefore prepared to denounce against him the sentence of excommunication. The college of cardinals was often assembled, in order to prepare the sentence with due deliberation; and the ablest canonists were consulted how it might be expressed with unexceptionable formality. At last it was issued on the 15th of June 1520. Forty-one propositions, extracted out of Luther's works, were therein condemned as heretical, scandalous, and offensive to pious ears; all persons were forbidden to read his writings, upon pain of excommunication; such as had any of them in their custody were commanded to commit them to the flames; he himself, if he did not, within sixty days, publicly recant his errors, and burn his books, was pronounced an obstinate heretic, excommunicated, and delivered to Satan for the destruction of the flesh; and all secular princes were required, under pain of incurring the same censure, to seize his person, that he might be punished as his crimes deserved.

Luther was not in the least disconcerted by this sentence, which he had for some time expected. He renewed his appeal to a general council; he declared the pope to be the antichrist, or man of sin, whose appearance is foretold in the New Testament; he declaimed against his tyranny with greater vehemence than ever; and at last, by way of retaliation, having assembled all the professors and students in the university of Wittemberg, with great pomp, and in the presence of a vast multitude of spectators, he cast the volumes of the canon law, together with the bull of excommunication, into the flames. The manner in which this action was justified gave still greater offence than the action itself. Having collected from the canon laws some of the most extravagant propositions with regard to the plenitude and omnipotence of the pope's power, as well as the subordination of all secular jurisdiction to his authority, he published these with a commentary, pointing out the impiety of such tenets, and their evident tendency to subvert all civil government.

On the accession of Charles V. to the empire, Luther found himself in a very critical situation. Charles, in order to secure the pope's friendship, had determined to treat him with great severity. His eagerness to gain this point rendered him not averse to gratify the papal legates in Germany, who insisted, that, without any delay or formal deliberation, the diet then sitting at Worms ought to condemn a man whom the pope had already excommunicated as an incorrigible heretic. Such an abrupt manner of proceeding, however, being deemed unprecedented and unjust by the members of the diet, they made a point of Luther's appearing in person, and declaring whether or not he adhered to those opinions which had drawn upon him the censures of the church. Not only the emperor, but all the princes through whose territories he had to pass, granted him a safe-conduct; and Charles wrote to him at the same time, requiring his immediate attendance on the diet, and renewing his promises of protection from any injury or violence. Luther did not hesitate one moment about yielding obedience, and set out for Worms, attended by the herald who had brought the emperor's letter and safe-conduct. Whilst on his journey, many of his friends, whom the fate of Huss, under similar circumstances, and notwithstanding the same security of an imperial safe-conduct, filled with solicitude, earnestly advised and entreated him not to rush wantonly into the midst of danger. But Luther, superior to such terrors, silenced them with this reply; "I am lawfully called to appear in that city; and thither will I go in the name of the Lord, though as many devils as there are tiles on the houses were there combined against me."

The reception which he met with at Worms was such as might have been reckoned a full reward of all his labours, if mere vanity and the love of applause had been the principles by which he was influenced. Greater crowds assembled to behold him than had appeared at the emperor's public entry; his apartments were daily filled with princes and personages of the highest rank; and he was treated with an homage more sincere, as well as more flattering, than any which pre-eminence in birth or condition can command. At his appearance before the diet, he behaved with decency and firmness. He readily acknowledged an excess of acrimony and vehemence in his controversial writings; but refused to retract his opinions unless he were convinced of their falsehood, or to consent to their being tried by any other rule than the word of God. When neither threats nor entreaties could prevail on him to depart from this resolution, some of the ecclesiastics proposed to imitate the example of the council of Constance, and, by punishing the author of this pestilent heresy, who was now in their power, to deliver the church at once from such an evil. But the members of the diet refused to expose German integrity to fresh reproach by a second violation of public faith, and Charles being no less unwilling to bring a stain upon the beginning of his administration by such an ignominious action, Luther was permitted to depart in safety. A few days after he had left the city, a severe edict was published in the emperor's name, and by authority of the diet, depriving him, as an obstinate and excommunicated criminal, of all the privileges which he enjoyed as a subject of the empire; forbidding any prince to harbour or protect him; and requiring all to seize his person as soon as the term specified in his protection should have expired.

But this vigorous decree had no considerable effect; the execution of it being prevented partly by the multiplicity of occupations which the commotions in Spain, together with the wars in Italy and the Low Countries, created to the emperor, and partly by a prudent precaution employed by the elector of Saxony, Luther's steady patron. As Luther, on his return from Worms, was passing near Altenstrain, in Thuringia, a number of horsemen in masks rushed suddenly out of a wood, where the elector had appointed them to lie in wait for him, and, surrounding his company, carried him, after dismissing all his attendants, to Wortburg, a strong castle not far distant. There the elector

Luther.

ordered him to be supplied with every thing necessary or agreeable; but the place of his retreat was carefully concealed, until the fury of the storm which had been raised against him began to abate, upon a change in the political system of Europe. In this solitude, where he remained nine months, and which he frequently called his *Patmos*, he exerted his usual vigour and industry in defence of his doctrines, or in confutation of his adversaries, publishing several treatises, which revived the spirit of his followers, who had been astonished and disheartened at the sudden disappearance of their leader.

Luther, weary at length of his retirement, re-appeared publicly at Wittemberg, upon the 6th of March 1522. This he did without the elector's leave, but he immediately wrote Frederick a letter to prevent his taking it amiss. The edict of Charles V., severe as it was, had given little or no check to Luther's doctrine; for the emperor had no sooner returned to Flanders than his edict was neglected, and the new doctrine seemed to spread even faster than before. In Luther's absence, Carolostadius had pushed on things faster than his leader; he had attempted to abolish the use of mass, to remove images out of the churches, to set aside auricular confession, invocation of saints, and the abstaining from meats; he had allowed the monks to leave their monasteries, to violate their vows, and to marry; in a word, he had quite changed the doctrine and discipline of the church at Wittemberg; all which, though not against Luther's sentiments, was yet blamed by him, as being rashly and unseasonably done. Lutheranism was still confined to Germany. It had not yet extended to France; and Henry VIII. of England passed the most rigorous acts to prevent it from invading his realm. Nay, he did something more. To show his zeal for religion and the holy see, and perhaps also to exhibit his skill in theological learning, he wrote a treatise on the Seven Sacraments, against Luther's book on the Captivity of Babylon, which he presented to Leo X. in October 1521. The pope received it very favourably, and was so well pleased with the king of England, that he complimented him with the title of Defender of the Faith. Luther, however, paid no regard to his rank as a sovereign, but answered him with great sharpness, treating both his person and performance in the most contemptuous manner. Henry complained of Luther's rude usage of him to the princes of Saxony; and Fisher, bishop of Rochester, replied to his answer, in support of Henry's treatise; but neither the king's complaint, nor the bishop's reply, was attended with any visible effects.

Luther, though he had put a stop to the more direct and honest proceedings of Carolostadius, now made open war with the pope and bishops; and, that he might induce the people to despise their authority, he wrote one book against the pope's bull, and another against the order called the Order of Bishops. The same year, 1522, he wrote a letter, dated the 29th of July, to the assembly of the states of Bohemia, in which he assured them that he was labouring to establish their doctrine in Germany, and exhorted them not to return to the communion of the church of Rome; and the same year he also published a translation of the New Testament in the German tongue, which was afterwards corrected by himself and Melancthon. This translation having been several times printed, and having passed into every body's hands, Ferdinand, archduke of Austria, the emperor's brother, issued a severe edict, to prevent the further publication of it; forbidding all the subjects of his imperial majesty to have any copies of it, or of Luther's other books, in their possession. Some other princes followed his example, and Luther was so incensed that he wrote a treatise on the secular power, in which he accused them of tyranny and impiety. The diet of the empire was held at Nuremberg, about the end of the year, and to it Adrian VI. sent his brief, dated the 25th of November; for Leo X. had died upon the 2d of December 1521, and Adrian had been elected pope upon the 9th of January following. In this brief he observes, amongst other things, to the diet, how he had heard with grief, that Martin Luther, after the sentence of Leo X. which had been ordered to be executed by the edict of Worms, continued to teach the same errors, and daily to publish books full of heresies; that it appeared strange to him, that so large and so religious a nation could be seduced by a wretched apostate friar; that nothing, however, could be more pernicious to Christendom; and therefore he exhorted them to use their utmost endeavours to make Luther, and the authors of these tumults, return to their duty, or, if they refused and continued obstinate, to proceed against them according to the laws of the empire, and the tenor of the last edict.

The resolution of this diet was published in the form of an edict, upon the 6th of March 1523; but it had no effect in checking the Lutherans, who still went on with undiminished boldness and confidence. This year Luther wrote a great many pieces, amongst which was one upon the dignity and office of the supreme magistrate, which Frederick, elector of Saxony, is said to have been highly pleased with. About the same time he sent a writing in the German language to the Waldenses in Bohemia and Moravia, who had applied to him about worshipping the body of Christ in the Eucharist. He also wrote another book, which he dedicated to the senate and people of Prague, concerning the institution of ministers of the church; and he drew up a form of saying mass. He wrote a piece entitled An Example of Popish Doctrine and Divinity, which Dupin calls "a satire against nuns, and those who profess a monastic life." He also wrote against the vows of virginity, in his preface to his commentary on 1 Corinthians, chap. viii.; and his exhortations were, it seems, followed with effects, for soon afterwards, nine nuns, amongst whom was Catharine de Bore, eloped from the nunnery at Nimptschen, and were brought, by the assistance of Leonard Coppen, a burgess of Torgau, to Wittemberg. Whatever offence this proceeding might give to the Catholics, it was highly extolled by Luther, who, in a book written in the German language, compares the deliverance of these nuns from the slavery of a monastic life, to that of the souls which Jesus Christ had delivered by his death. This year Luther had occasion to canonize two of his followers, who, as Melchior Adam relates, were burned at Brussels in the beginning of July, and were the first who suffered martyrdom for his doctrine. He likewise wrote a consolatory epistle to three noble ladies at Misnia, who had been banished from the Duke of Saxony's court at Friburg for reading his books.

In the beginning of the year 1524, Clement VII. sent a legate to the German diet, which was to be held at Nuremberg. Adrian VI. had died in October 1523, and, on the 19th of November, been succeeded by Clement. A little before his death, he canonized Benno, who had been bishop of Meissen in the time of Gregory VII. and one of the most zealous defenders of the holy see. Luther, imagining that this was done directly to oppose him, drew up a piece entitled Against the New Idol and Old Devil set up at Meissen; a production in which he treats the memory of Gregory with great freedom, and does not spare even that of Adrian. The legate of Clement VII. represented to the diet of Nuremberg the necessity of enforcing the execution of the edict of Worms, which had been strangely neglected by the princes of the empire; but, notwithstanding the legate's solicitations, which were very pressing, the decrees of the diet were thought so ineffectual, that they were condemned at Rome, and rejected by the emperor. In this year began the dispute between Luther and Erasmus, about free-will. Erasmus had been much courted by the Catholics to write against Luther; but he was all along of opinion that writing would not be found an effectual way to terminate the differences, and re-establish the peace of the church. However, overcome by the importunities of the pope and the Catholic princes, and desirous at the same time to clear himself from the suspicion of favouring a cause which he would not seem to countenance, he resolved to write against Luther, though, as he tells Melancthon, it was with some reluctance, and chose the subject of free-will as his theme. His book was entitled a Diatribe or Conference about Free-will, and was written with much moderation, and without personal reflections. In the preface, he tells Luther "that he ought not to take his dissenting from him in opinion ill, because he had allowed himself the liberty of differing from the judgment of popes, councils, universities, and doctors of the church." Luther was some time before he answered Erasmus's book, but at last he published a treatise *De Servo Arbitrio*, or of the Servitude of Man's Will; and though Melancthon had promised Erasmus that Luther should answer him with civility and moderation, yet Luther had so little regard to Melancthon's promise, that he never wrote any thing more severe. He accused Erasmus of being careless about religion, and little solicitous what became of it, provided the world continued in peace; and that his notions were rather philosophical than Christian. Erasmus immediately replied to Luther in a piece called *Hyperaspistes*, in the first part of which he answers his arguments, and in the second his personal reflections.

In October 1524, Luther threw off the monastic habit, which, though not premeditated or designed, was yet a very proper preparative to a step which he took the year following; we mean his marriage with Catharine de Bore. Catharine de Bore was a gentleman's daughter, who had been a nun, and was taken, as we have observed, out of the nunnery of Nimptschen, in the year 1523. Luther had a design, as Melchior Adam relates, to marry her to Glacius, a minister of Ortamunden; but she did not like Glacius, and so, on the 13th of June 1525, Luther married her himself. This conduct of his was severely blamed, not only by the Catholics, but, as Melancthon says, by those of his own party. He was even for some time ashamed of it himself, and owns that his marriage had made him so despicable, that he hoped his humiliation would rejoice the angels, and vex the devils. Melancthon found him so afflicted with what he had done, that he wrote some letters of consolation to him. It was not so much the marriage, as the circumstances of the time, and the precipitation with which it was constituted, that occasioned the censures which were passed upon Luther. He married all of a sudden, and at a time when Germany was groaning under the miseries of a war which was said to be owing to Lutheranism. Besides, it was thought to be an indecent thing in a man of forty-two years of age, who was then, as he professed, restoring the Gospel, and reforming mankind, to involve himself in marriage with a woman of twenty-six, either through incontinence, or upon any other account whatsoever. But Luther, as soon as he had recovered himself a little from this abasement, assumed his former air of intrepidity, and boldly supported what he had done. "I took a wife," says he, "in obedience to my father's commands; and hastened the consummation, in order to prevent impediments, and stop the tongues of slanderers." It appears, from his own confession, that he was much attached to Catharine de Bore, and used to call her by endearing names, which made profane people think and say wicked things of him. "And therefore," says he, "I married of a sudden, not only that I might not be obliged to hear the clamours which I knew would be raised against me, but to stop the mouths of those who reproached me with Catharine de Bore." Luther also gives us to understand that he did it partly as concurring with his grand scheme of opposing the Catholics.

Luther, notwithstanding, was not himself altogether satisfied with these reasons. He did not think the step which he had taken could be sufficiently justified upon the principles of human prudence; and therefore we find him, in other places, endeavouring to account for it from a supernatural impulse. But whether there was any thing divine in it or not, Luther found himself extremely happy in his new state, especially after his wife had brought him a son. "My rib Kate," says he in the joy of his heart, "desires her compliments to you, and thanks you for the favour of your kind letter. She is very well, through God's mercy. She is obedient and complying with me in all things, and more agreeable, I thank God, than I could have expected; so that I would not change my poverty for the wealth of Crœsus." According to Seckendorf, he had been heard to say, that he would not exchange his wife for the kingdom of France, nor for the riches of the Venetians, and that for three reasons; first, because she had been given him by God, at the time when he implored the assistance of the Holy Ghost, in finding a good wife; secondly, because, though she was not without faults, yet she had fewer than other women; and, thirdly, because she religiously observed the conjugal fidelity she owed him. At first a report was circulated that Catharine de Bore had been confined soon after her marriage with Luther; but Erasmus, who had communicated that piece of news to his friends, acknowledged a little afterwards that there was no foundation for the scandal. His marriage, however, did not retard his activity and diligence in the work of reformation. He revised the Augsburg Confession of Faith, and Apology for the Protestants, when the Protestant religion was first established on a firm basis.

After this, Luther had little else to do than to sit down and contemplate the mighty work which he had completed. That a single monk should have been able to give the church so rude a shock, that there needed but such another entirely to overthrow it, may very well seem a mighty work. Indeed he did little else; for the remainder of his life was spent in exhorting princes, states, and universities, to confirm the reformation which had been brought about through him; and in publishing from time to time such writings as might serve to encourage, direct, and aid them in doing so. The emperor threatened temporal punishment with armies, and the pope eternal damnation with bulls and anathemas; but Luther cared for none of their menaces. His friend and coadjutor Melancthon was not so indifferent; for he had in his composition a great deal of softness, moderation, and diffidence, which made him uneasy, and even sorrowful, on account of the present disorders. Hence we find many of Luther's letters written on purpose to support and comfort him under these natural distresses and anxieties.

In the year 1533, Luther wrote to the citizens of Oschatz, who had suffered some hardships for adhering to the Augsburg Confession of Faith, a consolatory epistle, in which, amongst other things, he says, "The devil is the host, and the world is his inn; so that wherever you come, you shall be sure to find this ugly landlord." He had also about this time a terrible controversy with George duke of Saxony, who had such an aversion to Luther's doctrine that he obliged his subjects to take an oath that they would never embrace it. However, sixty or seventy citizens of Leipzig were found to have deviated a little from the Catholic way in some point or other, and they were known previously to have consulted Luther about it; upon which George complained to the Elector John, that Luther had not only abused his person, but also preached up rebellion amongst his subjects. The elector ordered Luther to be made acquainted with this; and to be told at the same time, that if he did not clear himself of the charge, he could not possibly escape punishment. But Luther easily refuted the accusation, by proving that he had been so far from stirring up his subjects against him upon the score of religion, that, on the contrary, he had exhorted them to undergo the greatest hardships, and even suffer themselves to be banished, rather than offer any resistance.

The Bible translated by him into German was first printed in the year 1534, as the old privilege, dated at Bibliopolis, under the elector's hand, shows; and it was published the year after. He also published, the same year, a book against masses and the consecration of priests, in which he relates a conference he had with the devil upon those points; for it is remarkable in Luther's whole history, that he never had any conflicts of any kind within, but the devil was always his antagonist. In February 1537, an assembly was held at Smalcalde, about matters of religion, to which Luther and Melancthon were summoned. At this meeting Luther was seized with so grievous an illness that there seemed to be no hopes of his recovery. He was afflicted with the stone, and had a stoppage of urine for eleven days. In this terrible condition he must needs undertake to travel, notwithstanding all that his friends could say or do to prevent him. His resolution, however, was attended with a good effect; for the night after his departure he began to grow better. As he was carried along, he made his will, in which he bequeathed his detestation of popery to his friends and brethren, agreeably to what he often used to say, *Pestis eram vivus, moriens ero mors tua, papa;* "I was the plague of popery in my life, and shall continue to be so in my death."

This year the pope and the court of Rome, finding it impossible to deal with the Protestants by force, began to have recourse to stratagem. They therefore affected to think, that though Luther had indeed carried on things with a high hand, and to a violent extreme, yet that what he had pleaded in defence of these measures was not entirely without foundation. They talked with a seeming show of moderation; and Pius III. who had succeeded Clement VII. proposed a reformation first amongst themselves, and even went so far as to fix a place for a council to assemble for that purpose. But Luther treated this farce as it deserved; he unmasked and detected it immediately; and, to ridicule it the more strongly, he caused a picture to be drawn, in which were represented the pope seated on high upon a throne, some cardinals about him with foxes' tails on, and seeming *sursum deorsum repurgare*, as Melchior Adam expresses it. This gross design was fixed over against the title-page, to let the reader see at once the scope and object of the book, which was, to expose that cunning and artifice with which those subtile politicians affected to cleanse and purify themselves from their errors and superstitions. About the same time, Luther published a Confutation of the Pretended Grant of Constantine to Sylvester bishop of Rome, and also some letters of John Huss, written from his prison at Constance to the Bohemians.

In this manner was Luther employed until his death, which happened in the year 1546. His works were collected after his decease, and printed at Wittemberg in seven volumes folio.

LUTHERANISM, the opinions and doctrines of Martin Luther in regard to religion.

Lutheranism has undergone some alterations since the time of its founder. Luther rejected the epistle of St James, as inconsistent with the doctrine of St Paul relating to justification; and he also set aside the Apocalypse, both of which are now received as canonical in the Lutheran church. He reduced the number of sacraments to two, viz. Baptism and the Eucharist; but he believed in impanation, or the consubstantiation of the matter of the bread and wine with the body and blood of Christ; and it is in this article that the main difference consists between the Lutherans and English church.

Luther maintained that the mass was no sacrifice, and exploded the adoration of the host, auricular confession, meritorious works, indulgences, purgatory, the worship of images, and other observances which he considered as the growth of corrupt times. He also opposed the doctrine of free-will, maintained predestination, and asserted our justification to be solely by the imputation of the merits and satisfaction of Christ. He likewise opposed the fastings in the Roman Catholic church, monastical vows, the celibacy of the clergy, and many things besides.

LUTHERANS, the Christians who follow the opinions of Martin Luther, one of the principal reformers of the church in the sixteenth century.

The Lutherans, of all Protestants, are those who differ the least from the Catholic church; as they affirm that the body and blood of Christ are materially present in the sacrament of the Lord's Supper, though in an incomprehensible manner; and likewise represent some religious rites and institutions, such as the use of images in churches, the distinguishing vestments of the clergy, the private confession of sins, the use of wafers in the administration of the Lord's Supper, the form of exorcism in the celebration of baptism, and other ceremonies of a similar kind, as tolerable, and some of them as useful. With regard to the divine decrees, the Lutherans maintain that they respect the salvation or misery of men, in consequence of a previous knowledge of their sentiments and characters, and not as free and unconditional, and as founded on the mere will of God. Towards the close of the last century, the Lutherans began to entertain a greater liberality of sentiment than they had before adopted; although in many places they persevered longer in severe and despotic principles than other Protestant churches. Their public teachers now enjoy an unbounded liberty of dissenting from the decisions of those symbols or creeds which were once deemed almost infallible rules of faith and practice, and of declaring their dissent in the manner which they judge the most expedient. Mosheim attributes this change in their sentiments to the maxim which they generally adopted, that Christians were accountable to God alone for their religious opinions; and that no individual could be justly punished by the magistrate for his erroneous opinions, whilst he conducted himself as a virtuous and obedient subject, and made no attempts to disturb the peace and order of civil society.

LUTHERN, in *Architecture*, a kind of window over the cornice, in the roof of a building, standing perpendicularly over the naked of a wall, and serving to illuminate the upper story. Lutherns are of various forms; as square, semicircular, round, and so forth.

LUTON, a town of Bedfordshire, in the hundred of Flitt, thirty-one miles from London, and situated on the river Lea. There is a good market-house and a church, with a singular steeple formed of flints and freestone. Near it is the fine seat of the Marquis of Bute. It has some trade in thread-lace and straw-plait. The inhabitants amounted in 1801 to 3095, in 1811 to 3716, in 1821 to 4529, and in 1831 to 5693.

LUTTERWORTH, a market-town of the county of Leicester, in the hundred of Guthlaxton, eighty-nine miles from London, and near the ancient Roman Watling Street Road. It is not a place of much trade, but is distinguished as the residence of Wickliffe, the father of English Protestantism, who was priest of this place, and died here in 1387; and his doctrines were condemned by the council of Constance in 1418, in consequence of which his bones were taken from the grave, burned, and thrown into the river, in 1428. The pulpit from which he preached is still preserved as a valuable relic. There is a market which is held on Thursday. The population amounted in 1801 to 1652, in 1811 to 1845, in 1821 to 2102, and in 1831 to 2262.

LUXATION, is when any bone is moved out of its place of articulation, so as to impede or destroy its proper office or motion. See SURGERY.

LUXEMBURG, a grand duchy of Germany, under the government of the house of Orange Nassau. Before the French revolution, it comprehended the two duchies of Luxemburg and Bouillon; but on being conquered by France, it was divided by that power between the department of the Ardennes and that of the Forests. In consequence of the treaty of 1815 it assumed the present form. It extends in north latitude from 49. 26. to 50. 16. and in east longitude from 5. 1. to 6. 29., and contains 2378 square miles. At present it is bounded on the north by the province of Liège in the Netherlands, on the east by the Prussian province of the Lower Rhine, on the south and south-west by the French departments of the Moselle, the Meuse, and the Ardennes, and on the north-west by the Netherland province Namur. It is divided into three circles, and these into twenty-five cantons and 314 communes, with 255,600 inhabitants, who are partly Germans and partly Walloons, and all adhere to the Roman Catholic church. The surface is filled with hills and a few secondary mountains, and many extensive woods and heaths. The most pleasing and fruitful valleys are those in the arrondissement of the capital; the poorest and wildest, in that of Neufchatel. The chief river is the Moselle, which conveys to the Rhine the water of most of the smaller streams. The Ourthe rises in this province, but is an inconsiderable river till it enters France. The agriculture is in a backward state, and produces little corn, and that chiefly rye and winter barley; and though the cultivation of potatoes has been much extended, some importation is necessary to supply food in every year. The breed of horses is considerable, and though they are of small size, they are strong and active, and fit to mount light troops. The sheep are numerous, and the flesh of them of excellent flavour; but the wool is for the most part indifferent, though of late years some flocks have been improved by crosses with the Merino race. Fruit is abundant; a little wine is made, and a good quantity of cider from the apples and pears, from both of which, as well as from corn, much brandy is distilled. The iron mines afford employment to the population when their labours can be spared from the laborious work which their poor soil requires. The produce of the metal is about 10,000 tons yearly, which is mostly sent out of the duchy in a raw state, although the state of the roads is such as to make conveyance very expensive, except when from frost there is no other employment for the horses and men. A large quantity of slates for roofing houses is furnished, and in some parts the marshy spots supply much turf for fuel. The manufacturing industry is almost confined to linen spinning and weaving, and to making paper. The common articles of clothing and furniture are generally made within each department. The capital is the city of Luxemburg, one of the garrison towns of the German confederation, and commonly occupied by the troops of some of its members, most commonly Prussians. It is one of the most formidable fortresses in the world, both from the nature of its position, and the vast labour which has been applied to strengthen its natural capability of defence. The civil inhabitants are 9500, in 1500 houses, and depend partly on the money spent by the garrison, and partly on manufactures, the principal of which is tanning leather, and making glue, paper, and tobacco. The river Alzette or Elze runs by the fortifications, and supplies water to the inhabitants. Long. 6. 4. E. Lat. 49. 37. N.

LUXEMBURG, *François Henry de Montmorency*, duke of, and marshal of France, a renowned general in the service of Louis XIV. was born in 1628. He was with the Prince of Condé at the battle of Rocroi in 1643; and in 1668 he distinguished himself at the conquest of Franche Compté. In 1672 he commanded in chief the French army in Holland, when he defeated the enemy near Woerden and Bodegrave; and he was universally admired for the fine retreat which he effected in 1673. He became marshal of France in 1675; gained the battle of Fleurs in 1690, that of Steenkirk in 1692, and that of Nerwinde in 1693. He died at Versailles in 1695.

LUXEUIL, a city in the department of the Upper Saone, and arrondissement of Lure, in France. It is situated in a woody valley on the banks of the Breuchin, and is celebrated for its warm baths, as well as for a spring strongly impregnated with iron, all of which are much visited by invalids. About a quarter of a mile from the town are the remains of some magnificent baths constructed by the Romans. It contains 310 houses and 3200 inhabitants. Long. 6. 19. E. Lat. 47. 50. N.

LUXURIANS FLOS, a luxuriant or double flower, some of the parts of which are increased in number, to the diminution or entire exclusion of others.

The parts which are augmented or multiplied in luxuriant flowers, are the flower-cup and petals, which Linnæus considers as the teguments or covers of the flower; the parts which are diminished or entirely excluded are the stamina or chives, which the same author denominates the male organs of generation.

Luxuriance in flowers is capable of the three following varieties. 1. A flower is said to be multiplied (*flos multiplicatus*) when the increase of the petals is not such as to exclude all the stamina. In this sense, flowers are properly said to be double, triple, or quadruple, according to the number of multiplications of the petals. 2. A flower is said to be full (*flos plenus*) when, by the multiplication of the petals, all the stamina are excluded. Such are most of the double flowers which engage the attention of florists. 3. A flower is said to be prolific (*flos prolifer*) which produces flowers, and sometimes leaves, from its centre.

Many natural orders of plants do not in any circumstances produce luxuriant flowers. Of this kind are the masked flowers of Tournefort, excepting calf's-snout; and the rough-leaved, umbelliferous, starry plants, and such as flower at the joints, of Ray. Some umbelliferous flowers, however, are *prolific*. The pea-bloom or butterfly-shaped flowers are rarely rendered double; some instances, however, of luxuriance are observed in a species of lady's finger, coronilla, and broom.

All luxuriant flowers are vegetable monsters. Such as are perfectly full, by which we mean the greatest degree of luxuriance, cannot be propagated by seeds, because these, for want of impregnation, can never ripen. Full flowers therefore are very properly denominated by Linnæus *eunuchs*. This highest degree of luxuriance is very common in carnation, lychnis, anemone, stock, Indian cress, rose, marsh marigold, ranunculus, violet, peony, and narcissus.

Flowers which do not exclude all the stamina perfect their seeds. Of this kind are poppy, fennel-flower, campanula, and some others. Some flowers, as those of the water-lily, fig-marigold, and cactus, have many rows or series of petals, without the number of stamina being in the least diminished. Such flowers are not to be reckoned luxuriant in the slightest degree. Luxuriance in flowers is generally owing to excess of nourishment.

LUXURY, voluptuousness, or an extravagant indulgence in diet, in dress, and in equipage.

Luxury, amongst the Romans, prevailed to such a degree that several laws were made to suppress, or at least restrict it. The extravagance of the table commenced about the time of the battle of Actium, and continued in great excess until the reign of Galba. Peacocks, cranes of Malta, nightingales, venison, wild and tame fowl, were considered as delicacies. A profusion of provisions was the reigning taste. Whole wild boars were often served up, and sometimes they were filled with various small animals, and birds of different kinds; a dish which they called the *Trojan horse*, in allusion to the wooden horse filled with soldiers. Fowls and game of all sorts were served up in pyramids, piled up in dishes as broad as moderate tables. Lucullus had a particular name for each apartment; and in whatever room he ordered his servants to prepare the entertainment, they knew by the direction the expense to which they were to go. When he supped in the Apollo, the expense was fixed at 50,000 drachmæ, that is L.1250. Marc Antony provided eight boars for twelve guests. Vitellius had a large silver platter, called *Minerva's Buckler*, which is said to have cost a million of sesterces. In this he blended together the livers of gilt-heads, the brains of pheasants and peacocks, the tongues of phenicopters, and the milts of lampreys. Caligula served up to his guests pearls of great value dissolved in vinegar; and the same was also done by Clodius the son of Æsop the tragedian. Apicius laid aside ninety millions of sesterces, besides a mighty revenue, for no other purpose but to be sacrificed to luxury; but finding himself involved in debt, he looked over his accounts, and though he had the sum of ten millions of sesterces still left, he poisoned himself from fear of being starved to death.

The Roman laws to restrain luxury were the *Leges Orchia, Fannia, Didia, Licinia, Cornelia*, and many others. But all these were unavailing; for as riches increased amongst them, so did sensuality.

What were the ideas of luxury entertained in England about two centuries ago, may be gathered from the following passage, contained in a discourse prefixed to Holinshed's Chronicles. " Neither do I," says the writer of this discourse, " speak this in reproach of any man, God is my judge; but to show, that I do rejoice, rather to see how God has blessed us with his good gifts, and to behold how that in a time wherein all things are grown to the most excessive prices, we yet do find means to obtain and atchieve such furniture as heretofore was impossible. There are old men yet dwelling in the village where I remain, which have noted three things to be marvellously altered in England within their sound remembrance. One is the multitude of chimneys lately erected; whereas in their young days there were not above two or three, if so many, in most uplandish towns of the realm (the religious houses, and manor places of their lords, always excepted, and peradventure some great personages), but each made his fire against a reredoss [screen] in the hall, where he dressed his meat and dined. The second is the great amendment of lodging; for, said they, our fathers and we ourselves have lain full oft upon straw pallets covered only with a sheet, under coverlits made of a dogswaine or horharriots (to use their own terms), and a good log under their head instead of a bolster. If it were so that the father or goodman of the house had a mattrass, or flock bed and sheets, with a sack of chaff to rest his head upon, he thought himself to be as well lodged as the lord of the town. So well were they contented, that pillows (said they) were thought meet only for women in childbed; as for servants, if they had any sheet above them, it was well; for seldom had they any under their bodies to keep them from pricking straws, that ran oft through the canvas and their hardened hides. The third thing they tell of, is the exchange of treene [wooden] platters into pewter, and wooden spoons into silver or tin; for so common were all sorts of treene vessels in old times, that a man should hardly find four pieces pewter (of which one was peradventure a salt) in a good farmer's house. Again, in times past, men were contented to dwell in houses builded of sallow, willow, &c. so that the use of oak was in a manner dedicated wholly unto churches, religious houses, princes palaces, navigation, &c. But now willow, &c. are rejected, and nothing but oak anywhere regarded; and yet see the change, for when our houses were builded of willow, then had we oaken men; but now that our houses are come to be made of oak, our men are not only become willow, but a great many altogether of straw, which is a sore alteration. In these the courage of the owner was a sufficient defence to keep the house in safety; but now the assurance of the timber must defend the men from robbing. Now have we many chimneys, and yet our tenderlins complain of rheums, catarrhs, and poses; then had we none but reredoses, and our heads did never ache. For as the smoke in those days were supposed to be sufficient hardening for the timber of the house; so it was reputed a far better medicine to keep the goodman and his family from the quacks or pose; wherewith, as then, very few were acquainted. Again, our pewterers in time past employed the use of pewter only upon dishes and pots, and a few other trifles for service; whereas now they are grown into such exquisite cunning, that they can in a manner imitate by infusion any form or fashion of cup, dish, salt, bowl, or goblet, which is made by the goldsmith's craft, though they be ever so curious and very artificially forged. In some places beyond the sea, a garnish of good flat English pewter (I say flat, because dishes and platters in my time began to be made deep, and like basons, and are indeed more convenient both for sauce and keeping the meat warm) is esteemed so precious as the like number of vessels that are made of fine silver."

Particular instances of luxury, in eating, however, might be produced from an earlier period, and would be found to surpass even the extravagance of the Romans. Thus, in the tenth year of the reign of Edward IV., 1470, George Nevill, brother to the Earl of Warwick, at his instalment into the archiepiscopal see of York, entertained most of the nobility and principal clergy, when his bill of fare was 300 quarters of wheat, 350 tuns of ale, 104 tuns of wine, a pipe of spiced wine, eighty fat oxen, six wild bulls, 1004 weathers, 300 hogs, 300 calves, 3000 geese, 3000 capons, 300 pigs, 100 peacocks, 200 cranes, 200 kids, 2000 chickens, 4000 pigeons, 4000 rabbits, 204 bitterns, 4000 ducks, 200 pheasants, 500 partridges, 200 woodcocks, 400 plovers, 100 curlews, 100 quails, 1000 egrets, 200 rees, 400 bucks, does, and roebucks, 1506 hot venison pasties, 4000 cold ditto, 1000 dishes of jelly parted, 4000 dishes of jelly plain, 4000 cold custards, 2000 hot custards, 300 pikes, 300 breams, eight seals, four porpuses, 400 tarts. At this feast the Earl of Warwick was steward, the Earl of Bedford treasurer, and Lord Hastings comptroller, with many more noble officers; and there were 1000 servitors, 62 cooks, 515 menial apparitors in the kitchen. But such was the fortune of the man, that after his extreme prodigality, he died in the most abject but unpitied poverty, *vinctus jacuit in summa inopia.*

And as to *dress*, luxury in that article seems to have attained a great height long before Holinshed's time. For in the reign of Edward III. we find no fewer than seven sumptuary laws passed in one session of parliament to restrain it. It was enacted, that men-servants of lords, as also of tradesmen and artisans, shall be content with one meal of fish or flesh every day; and the other meals, daily, shall be of milk, cheese, butter, and the like. Neither shall they use any ornaments of gold, silk, or embroidery; nor their wives and daughters any veils above the price of twelvepence. Artisans and yeomen shall not wear cloth above 40s. the whole piece (the finest then being about L.6 per piece), nor the ornaments before named;

nor the women any veils of silk, but only those of thread made in England. Gentlemen under the degree of knights, not having L.100 yearly in land, shall not wear any cloth above $4\frac{1}{2}$ marks the whole piece. Neither shall they or their females use cloth of gold, silver, or embroidery. But esquires having L.200 per annum or upwards of rent may wear cloths of five marks the whole piece of cloth; and they and their females may also wear stuff of silk, silver, ribbons, girdles, or furs. Merchants, citizens, burghers, and artificers or tradesmen, as well of London as elsewhere, who have goods and chattels of the clear value of L.500, and their females, may wear as is allowed to gentlemen and esquires of L.100 per annum. And merchants, citizens, and burgesses, worth above L.1000 in goods and chattels, and their females, may wear the same as gentlemen of L.200 per annum. Knights of 200 marks yearly may wear cloth of six marks the cloth, but no higher; but no cloth of gold, nor furred with ermine: but all knights and ladies having above 400 marks yearly, up to L.1000 per annum, may wear as they please, ermine excepted; and they may wear ornaments of pearl and precious stones for their heads only. Clerks having degrees in cathedrals, colleges, may wear as knights and esquires of the same income. Ploughmen, carters, shepherds, and such like, not having 40s. value in goods or chattels, shall wear no sort of cloth but blanket and russet lawn at 12d. and shall wear girdles and belts; and they shall only eat and drink suitable to their stations. And whosoever uses other apparel than is prescribed by the above laws shall forfeit the same.

Concerning the general utility of luxury to a state, there is much difference of opinion amongst political writers. Montesquieu asserts, that luxury is necessary to monarchies, as in France, but that it is ruinous to democracies, as in Holland. With regard, therefore, to Britain, whose government is compounded of both species, it is held to be a dubious question, how far private luxury is a public evil, and, as such, cognizable by public laws; and indeed our legislators have several times changed their sentiments as to this point; for formerly there were a number of penal laws existing to restrain excess in apparel, chiefly made in the reigns of Edward III. IV. and Henry VIII. a specimen of which we have inserted above. But all of them it appeared expedient to repeal at an after period. In fact, although luxury will of necessity increase according to the influx of wealth, it may not be for the general benefit of commerce to impose, as in the above-cited laws, an absolute prohibition of every degree of it; yet, for the good of the public, it may be necessary that such as go beyond proper bounds in eating, drinking, and wearing what by no means is suitable to their station, should be taxed accordingly, could it be done without including those who have a better title to such indulgence. This is certainly, however, a point which should be maturely weighed before it be executed; and, in mercantile countries at least, such restraints may be found prejudicial, most likely impracticable, especially where true liberty is established. Sir William Temple observes, speaking of the trade and riches, and at the same time of the frugality, of the Hollanders, "That some of our maxims are not so certain as current in politics; as that encouragement of excess and luxury, if employed in the consumption of native commodities, is of advantage to trade. It may be so to that which impoverishes, but not to that which enriches, a country. It is indeed less prejudicial if it lies in native than in foreign wares; but the humour of luxury and expense cannot stop at certain bounds; what begins in native will proceed to foreign commodities; and though the example arise among idle persons, yet the imitation will run into all degrees, even of those men by whose industry the nation subsists. And besides, the more of our own we spend, the less shall we have to send abroad; and so it will come to pass, that while we drive a vast trade, yet, by buying much more than we *sell*, we shall come to be poor at last."

LUZIN, a circle of the Russian province Witebsk, extending in north latitude from 55. 55. to 57. 15. and in east longitude from 27. 1. to 27. 29. It contains one city and 1227 villages, with 32,300 inhabitants. The capital is a small town of the same name, situated on the river Welika, 390 miles from St Petersburg. Long. 38. 35. E. Lat. 56. 35. N.

LUZK, a circle of the province of Volhynia, in Russia, extending in north latitude from 50. 33. to 51. 34. and in east longitude from 25. 4. to 25. 37. The northern part is marshy, the southern very fertile. The capital is a city of the same name, situated on the river Styr, 1126 miles from St Petersburg. It contains one Catholic and several Greek churches, 600 houses, and 3150 inhabitants. Long. 25. 5. E. Lat. 50. 44. N.

LUZON, Lucon, or Luconia, one of the Philippine islands, and the largest of the whole group, situated between the thirteenth and nineteenth degrees of north latitude, and extending from the 120th to the 124th degrees of east longitude. It is 400 miles in length, by 115 in average breadth. The greater part of this island is mountainous, being intersected in its whole length from north to south by an elevated chain, from which diverge various ramifications and detached mountains of a conical figure, in the midst of extensive plains. The soil is remarkably fertile, and the climate for the most part moist; but it is temperate, considering the situation of the island within the tropics. It yields cotton, indigo, sugar, tobacco, and generally all sorts of tropical produce, the richest fruits of the West as well as of the East Indies, and, with ordinary industry, would rival the Moluccas in the production of spices and precious aromatics. In the mountains are found wild cinnamon, nutmegs, ebony, sandal wood, together with excellent timber for building and shipping. Gold is washed down from the higher grounds, and is found among the sands and mud of its rivers, brooks, and lakes. Civet cats are common, and ambergris is thrown on the coast in prodigious quantities. There are several volcanoes on the island, and many warm springs and small lakes, indicating an internal combustion, from which probably originate the earthquakes to which the island is subject. In 1650 one of these earthquakes overturned almost all the city of Manilla; and in 1754 another took place, which was attended with the most destructive effects. The coast is indented by many bays and commodious harbours; that of Manilla is the finest in the world, and is the only one frequented by ships of burden. The Spaniards on their arrival found upon the coast a nation of Moors, who called themselves Tagalians, and were Malayans by descent. They are for the most part a quiet and tractable people. After their conquest by the Spaniards they were most cruelly oppressed by monopolies and other tyrannical restraints; the population of the country was diminished, agriculture discouraged, and the inhabitants, destitute of any motive to energy, have sunk into indolence. Manilla is the capital. The population is estimated at 900,000, though nothing certain is known on this subject.

LYBIA, or Libya, a name anciently given to all that part of Africa lying between the borders of Egypt and the river Triton, and comprehending *Cyrenaica*, *Marmarica*, and the *Regio Syrtica*. See Ethiopia.

LYCÆUM, Λυκειον, in *Antiquity*, the name of a celebrated school or academy at Athens, where Aristotle explained his philosophy. The place was composed of porticos and trees planted in the quincunx form, where the philosophers disputed walking. Hence the philosophy of the Lycæum is used to signify the philosophy of Aristotle, or the peripatetic philosophy. Suidas observes, that the Lycæum took its name from its having been originally a temple of Apollo Lycæus, or rather a portico or gallery built by Lycæus, son of Apollo; but others state that it had been built either by Pisistratus or by Pericles.

LYCAON, in fabulous history, the first king of Arcadia, son of Pelasgus and Melibœa. He built a town called Lycosura, upon the top of Mount Lycæus, in honour of Jupiter. He had many wives, by whom he had a daughter called Callisto, and fifty sons. He lived about 1820 years before the Christian era, and was succeeded on the throne by Nyctimus, the eldest of his sons. This is also the name of another king of Arcadia, celebrated for his cruelties. He was changed into a wolf by Jupiter, because he had offered human victims upon the altar of the god Pan. Some attribute this metamorphosis to another cause. The sins of mankind, as they relate, had become so enormous, that Jupiter, having visited the earth in order to punish its impiety and wickedness, came to Arcadia, where he was announced as a god, and the people began to pay proper adoration to his divinity. But Lycaon, who used to sacrifice all strangers to his wanton cruelty, laughed at the pious prayers of his subjects, and, to try the divinity of the god, he served up human flesh on his table. This impiety so irritated Jupiter that he immediately destroyed the house of Lycaon, and changed him into a wolf.

LYCIA, a country of Asia Minor, bounded by the Mediterranean on the south, by Caria on the west, by Pamphylia on the east, and by Phrygia on the north. It was anciently called *Milyas* and *Tremile*, from the Milyæ or Solymi, a people of Crete, who came to settle there. The country received the name of *Lycia* from Lycus, the son of Pandion, who there established himself. The inhabitants have been greatly commended by all the ancients for their sobriety and justice. They were conquered by Crœsus, king of Lydia, and afterwards by Cyrus. Though they were subject to the power of Persia, yet they were governed by their own kings, and only paid a yearly tribute to the Persian monarch. When Alexander marched into the East, they became part of the Macedonian empire, and afterwards were ceded to the house of the Seleucidæ. The country was reduced into a Roman province by the Emperor Claudius.

LYCODONTES, the petrified teeth of the lupus-piscis, or wolf-fish, frequently found in a fossil state. They are of different shapes; but the most common kind swell out in a semi-orbicular form, and are hollow within, somewhat resembling an acorn-cup. This hollow is found sometimes empty, and sometimes filled with the stratum in which it was imbedded. Many of them have an outer circle of a different colour from the rest.

LYCOMEDES, in fabulous history, a king of Scyros, an island in the Ægean Sea. He was son of Apollo and Parthenope, and was secretly intrusted with the care of young Achilles, whom his mother Thetis had disguised in woman's clothes, in order to prevent him proceeding to the Trojan war, where she knew he must unavoidably perish. Lycomedes rendered himself famous for his treachery to Theseus, who had implored his protection when driven from the throne of Athens by the usurper Mnestheus. Lycomedes, as is reported, either envious of the fame of his illustrious guest, or bribed by the emissaries of Mnestheus, led Theseus to an elevated place, on the pretence of showing him the extent of his dominions, and perfidiously threw him down a precipice, by which means he was killed.

LYCON, a philosopher of the school of Aristotle, was a native of Loadicea, in Phrygia. He was born B. C. 300, and died, at the age of seventy-four, B. C. 226. Upon the death of Strato, Lycon became the head of the Aristotelian sect (B. C. 270), and taught the school at Athens which had been conducted successively by Aristotle, Theophrastus, and Strato, whom he succeeded. We are informed by Diogenes Laertius, in his life of this philosopher, that he was particularly successful in directing the studies of youth; and that he regarded corporal punishment as not only useless, but positively injurious, holding, that youth ought to be directed by feelings of honour and shame, as a horse is by the spur and reins. His eloquence was full of mild persuasion, and so melodious, that his contemporaries prefixed the letter *G* to his name, making it Glycon, which signifies *sweetness.* He was much esteemed by Attalus and Eumenes I. kings of Pergamus; and Antiochus, king of Syria, did every thing in his power to prevail on him to remain at his court. He conducted the school with great ability during upwards of forty-two years, and was succeeded by Aristo Ceus (Plut. *Mor.* p. 605, B.). The last will of Lycon is given by Diogenes, and exhibits a strong proof of the kindness and goodness of his nature.

LYCOPHRON, a Greek poet, was a native of Chalcis, a city in the island of Eubœa, and the son of Socles; but of his private history we are almost entirely ignorant. It is supposed that Lycophron began to be distinguished in the beginning of the reign of Philadelphus, B. C. 280, and continued to rise in reputation till B. C. 250, during the first years of the first Punic war, a period of thirty years. If we be correctly informed respecting the mode in which he acquired the friendship and favour of Ptolemy Philadelphus, who then held his court at Alexandreia, it is not much to the credit of Lycophron. It is said that he owed it to the flattering compliments he contrived to convey to the prince through ingenious anagrams. Thus, from Πτολεμαιος, he made ἀπο μελιτος (*of honey*); in Arsinoe, the name of the queen, he found ἰον Ἡρας (*violet of Juno*). Lycophron is included amongst those seven poets who from their number were called the Pleias. They were all contemporary, and all graced the court of Philadelphus. Their names were, Homerus, Sositheus, Lycophron, Alexander (Ætolus), Philiseus, Sosiphanes or Dionysides, and Æantides. Lycophron was the author of sixty-four, or, according to others, of forty-six, tragedies (Tzetzes *ad Lyc.* p. 270). Suidas gives the names of nineteen of them. They have all however disappeared, and the only fragment of them that has been preserved is a verse of four lines of his tragedy entitled *Pelopidæ*, by Stobæus. The idea is beautiful, and is expressed with great simplicity. "The unhappy call upon death to relieve them while he is at a distance; but when the last moments of life approach, we are anxious to live. Man is never tired of life." Lycophron is also said to have been the author of satires, one of which, directed against Menedemus, and where he ridiculed the frugal table of this founder of the Eretrian school, has been particularly mentioned. (*Athen.* x. p. 420; xi. p. 55.) He also wrote some books on comedy; but the work which has been preserved, and for which he is best known, is entitled *Alexandra* or *Cassandra*, from the daughter of Priam, who had two appellations, like her brother Paris. The poem consists of 1474 lines. Cassandra had acquired by a trick the power of prophecy from Apollo; but, having refused to fulfil her engagement, the god prevented any credit being attached to her words, and caused her to be regarded as mad. She is shut up in a tower by Priam, that she may not alarm the city, and from the summit of the tower she observes the vessel depart which bore Paris to the shores of Greece. This spectacle excites her prophetic powers, and a servant who overhears her words repeats them to Priam. She commences by deploring the fate which she foresees must inevitably overtake her native city, and then proceeds to foretell the various calamities which will arise out of the Trojan war. She first recounts those which will befall Helen, her parents, brothers, and sisters; and then notices the fates of the different Grecian leaders, such as Ajax, Diomede, Menelaus, Agamemnon, and Idomeneus. This causes her to

Lycurgia
||
Lycurgus.

refer to the numerous wars which had been carried on at various times between the inhabitants of Europe and Asia. She begins with the rape of Io and Europa, and, giving an historical sketch of the Argonauts, the Amazons, the Trojans, Midas, and Xerxes, she brings down her history to the time of Alexander the Great. Besides, there are many episodes scattered throughout the work, such as the Labours of Hercules, the Deluge of Deucalion, the Wanderings of Æneas, and the colony planted in Latium. This work of Lycophron is one of the most obscure which antiquity has handed down to us, and it appears that the author exerted all his ingenuity to render it so. He has succeeded principally by the employment of unusual modes of syntax, of rare and obsolete words, of expressions far removed from the common dialect, of confused metaphors, and of periods so involved that the reader loses himself in a labyrinth of words. There have been many commentaries on the Alexandra, but the best is that by Tzetzes. The best edition is that of Potter (Oxford, 1697, 1702), in which the text is accompanied by the scholia of Tzetzes, the remarks of Canter and Meursius, and a valuable index. Reichard (Lip. 1788), rejecting the commentaries of Tzetzes, Meursius, and Potter, published the simple text and notes of Canter, adding a continued paraphrase like that which is found in the editions of the classics ad usum Delphini. The Scholia have been published separately by Müller (3 vols. Lips. 1811), Royston translation.

LYCURGIA, a festival observed by the Spartans, in memory of their lawgiver Lycurgus, whom they honoured with a temple and an annual sacrifice.

LYCURGUS, the celebrated legislator of the Spartans, was the son of Eunomes, king of Sparta. He travelled in Greece, the island of Crete, Egypt, and even proceeded to the Indies, to converse with the sages and learned men of those countries, and to learn their manners, customs, and laws. After the death of his brother Polydectes, who was king of Sparta, his widow offered the crown to Lycurgus, promising that she would cause herself to miscarry of the child of which she was pregnant, provided he would marry her; but Lycurgus nobly refused these advantageous offers, and afterwards contented himself with being tutor to his nephew Charillus, whom he restored to the government when he came of age. Notwithstanding this honourable and generous conduct, however, he was accused of a design to usurp the crown. This calumny obliged him to retire to the island of Crete, where he applied himself to the study of the laws and customs of nations. On his return to Lacedæmon, he reformed the government, and, to prevent the disorders occasioned by luxury and the love of riches, he prohibited the use of gold and silver; placed all the citizens in a state of equality; and introduced the strictest temperance, the most exact discipline, and those remarkable laws which, with few exceptions, have been celebrated by all historians. It is said, that, to engage the Lacedæmonians to observe them inviolably, he made them promise upon oath not to change any part of them till his return; and that he afterwards went to the island of Crete, where he killed himself, having ordered that his ashes should be thrown into the sea, from fear lest, if his body should be carried to Sparta, the Lacedæmonians would think themselves absolved from their oath. He flourished about 870 B. C.

LYCURGUS, one of the most celebrated orators of Greece, was born at Athens about the year B. C. 400, and died about B. C. 323. He was son of Lycophron, and grandson of Lycurgus, one or other of whom was put to death by the Thirty Tyrants, B. C. 404 (Phot. *Cod.* cclxviii. p. 1483). In his early years he studied philosophy under Plato, and the political constitution of his country under Isocrates. At what period he entered upon public life is nowhere recorded, but we find him, B. C. 343, appointed, along with Demosthenes, one of the ambassadors to counteract the proceedings of Philip in different parts of Greece (Demosth. *Philipp.* iii. p. 129). So much confidence had his fellow-citizens in his integrity, that he continued to preside over the collection of the public revenue for twelve or fifteen years. After the defeat of the Greeks at the battle of Chæronea, B. C. 338, he brought Lysicles, the general of the Athenians on that occasion, to trial before the people, and procured his condemnation (Diodor. Sicul. xvi. 88). He restored the credit of comic exhibitions at the Lenæan festival, and enacted honours for the three great tragic poets (*Vit.* x. Or. p. 841). Lycurgus was one of the orators demanded by Alexander, after the destruction of Thebes, B. C. 335; but the Athenians refused to give him up (Plut. *Demosth.* c. 23; Arrian, *Exp.* i. 10). It would appear that Lycurgus died about the time of the exile of Demosthenes, B. C. 323, the year before that orator's death (*Vit.* x. Or. p. 842). There were fifteen orations of Lycurgus extant in the time of Plutarch and Photius, but only one has been preserved (against Leocrates), which was delivered B. C. 330. It is published by Hauptmann (Lips. 1751), by Schulze (Bruns. 1789), by Osann (Jena, 1821), and, along with other fragments, by Bekker (Magdeb. 1821).

Lydd
||
Lydia.

LYDD, a market-town of the county of Kent, in the hundred of Langport and lathe of Shepway, seventy-three miles from London. It is in a low situation, on Romney Marsh; and is a member of the Cinque Ports, near the sea. It has a small market, which is held on Thursday. The population amounted in 1801 to 1303, in 1811 to 1504, in 1821 to 1437, and in 1831 to 1357.

LYDGATE, JOHN, surnamed the *Monk of Bury*, not, as Cibber conjectures, because he was a native of that place, for he was born about the year 1380, in the village of Lydgate, but because he was a monk of the Benedictine convent at St Edmund's-Bury. After studying some time in the English universities, he travelled into France and Italy; and, having thus acquired a competent knowledge of the languages of those countries, he returned to London, where he opened a school, in which he instructed the sons of the nobility in polite literature. At what time he retired to the convent of St Edmund's-Bury, does not appear; but he was certainly in that establishment in the year 1415. He was alive in 1446, when he must have been about sixty-six years of age; but in what year he died is not known. Lydgate, according to Pits, was an elegant poet, a persuasive rhetorician, an expert mathematician, an acute philosopher, and a respectable divine. He was a voluminous writer, and, considering the age in which he lived, an excellent poet. His language is less obsolete, and his versification more harmonious, than the language and versification of Chaucer, who wrote about half a century before his time. His works are, 1. History of the Theban War, printed at the end of Chaucer's works, 1561, 1602, 1687; 2. Poemation of Good Counsel, at the end of Chaucer's works; 3. The Life of Hector, London, 1594, folio, printed by Gross, and dedicated to Henry V.; 4. Life of the Blessed Virgin, printed by Caxton; 5. The Proverbs of Lydgate upon the fall of princes, printed by Winkyn de Worde, London, 4to; 6. Dispute of the Horse, the Sheep, and the Goose, printed in Caxton's Collect. 4to; 7. The Temple of Brass, amongst the works of Chaucer; 8. London Lickpenny (vide Stow's *History*); besides an incredible number of other poems and translations preserved in various libraries.

LYDIA, in *Ancient Geography*, a celebrated kingdom of Asia Minor. The ancient writers inform us, that Lydia was first called *Mæonia* or *Meonia*, from Meon, king of Phrygia and Lydia; and that it was known under no other denomination until the reign of Atys, when it began to be called *Lydia*, from his son Lydus. Bochart, finding in his learned collection of Phœnician words the verb *Luz*, signifying "to wind," and observing that the country we are speaking of is watered by the Mæander, so famous for its windings, concludes that it was thence named *Ludia* or *Lydia;* but this, it must be obvious, is too fanciful and remote a derivation to be the true one. As to the ancient name of Mæonia, he takes it to be a Greek translation of the Phœnician word *lud*, in which he agrees in some measure with Stephanus, who derives the name of Mæonia from Mæon, the ancient name of the Mæander. Some take the word *Mæonia* to be a translation of a Hebrew word signifying metal, because, according to them, that country was in former times rich above any other with mines. Though Lydia and Mæonia are by most authors indifferently used for one and the same country, yet they are sometimes distinguished; that part including Mount Tmolus, and watered by the Pactolus, being properly called *Mæonia;* and the other, situated upon the coast, *Lydia*. This distinction is observed by Homer, Callimachus, Dionysius, and other ancient writers. In after ages, when the Ionians, who had planted a colony on the coast of the Ægean Sea, began to make some figure, that part was called *Ionia*, and the name of *Lydia* given to the ancient Mæonia. Lydia, according to Pliny, Ptolemy, and other ancient geographers, was bounded by Mysia Major on the north, by Caria on the south, by Phrygia Major on the east, and by Ionia on the west, and was situated between the thirty-seventh and thirty-ninth degrees of north latitude. But what the ancients style the kingdom of *Lydia* was not confined within these narrow boundaries; it extended from Halys to the Ægean Sea. Pliny's description includes Æolia, situated between the Hermus and the Caïcus.

As to the origin of the Lydians, Josephus, and after him all the ecclesiastical writers, derive them from Lud, Shem's fourth son; but this opinion has no other foundation than the similitude of names. Some of the ancients conceive the Lydians to have been a mixed colony of Phrygians, Mysians, and Carians; but others, finding some conformity in religion and religious ceremonies between the Egyptians and Tuscans, who were a Lydian colony, conclude, without further evidence, that they were originally Egyptians. All we know for certain is, that the Lydians were a very ancient nation; and this is manifest from their fables; for Atys, Tantalus, Pelops, Niobe, and Arachne, are all said to have been the children of Lydus. Zanthus, in his *Lydiaca*, quoted by Stephanus, informs us, that the ancient city of Ascalon, one of the five satrapies of the Philistines, mentioned in the books of Joshua and the Judges, was built by one Ascalus a Lydian, whom Achiamus, king of Lydia, had appointed to command a body of troops which he sent into Syria, we know not on what occasion. The Heraclidæ, or kings of Lydia descended from Hercules, began to reign before the Trojan war, and had been preceded by a long line of sovereigns sprung from Atys, and hence styled *Atyadæ;* a strong proof of the antiquity of that kingdom.

The Lydians began very early to be governed by kings, whose authority seems to have been despotic, and the crown hereditary. We read of three distinct races of kings reigning over Lydia; the Atyadæ, the Heraclidæ, and the Mermnadæ. The *Atyadæ* were so called from Atys the son of Cotys, and grandson of Manes the first Lydian king. But the history of this family is obscure and fabulous. The Atyadæ were succeeded by the *Heraclidæ*, or the descendants of Hercules. This hero having, by the direction of the oracle, been sold as a slave to Omphale, queen of Lydia, in order to expiate the murder of Iphitus, had, by one of her slaves, during his captivity, a son named Cleolaus, whose grandson Argon was the first of the Heraclidæ who ascended the throne of Lydia. This race is said to have reigned 505 years, the son succeeding the father for twenty-two generations. They began to reign about the time of the Trojan war. The last of the family was the unhappy Candaules, who lost both his life and kingdom by his imprudence. Of this event an account is given by Herodotus. Candaules had a wife whom he passionately loved, and believed to be the most beautiful of her sex. He extolled her charms to Gyges his favourite, whom he used to intrust with his most important affairs; and, to convince him the more of her beauty, resolved to show her to him quite undressed. He accordingly placed Gyges in the porch of the chamber where the queen used to undress when she went to bed, ordering him to retire after he should have seen her, and take the utmost possible care not to be observed. But notwithstanding all the caution he employed, she plainly discovered him going out; and though she did not doubt that it was her husband's contrivance, yet she passed that night in seeming tranquillity, suppressing her resentment till next morning, when she sent for Gyges, and resolutely told him that he must either by his death atone for the criminal action he had been guilty of, or put to death Candaules, the contriver of it, and receive both her and the kingdom of Lydia as his reward. Gyges at first earnestly begged of her that she would not drive him to the necessity of such a choice; but finding that he could not prevail with her, and that he must either kill his master or be killed himself, he chose the former part of the alternative. Being led by the queen to the same place where her husband had posted him the night before, he stabbed the king whilst he was asleep, married the queen, and took possession of the kingdom, in which he was confirmed by the response of the oracle of Delphi. But the Lydians having taken up arms to revenge the death of their prince, an agreement was made between them and the followers of Gyges, that if the oracle should declare him to be lawful king of Lydia, he would be permitted to reign; if not, that he should resign the crown to the Heraclidæ. The answer of the oracle proved favourable to Gyges, and he was universally acknowledged as lawful king of Lydia. Candaules is said to have purchased, for its weight in gold, a picture painted by Bularchas, representing a battle of the Magnetes; a circumstance which shows how early the art of painting had begun to be appreciated in that country, Candaules having been contemporary with Romulus.

Gyges, having thus possessed himself of the kingdom of Lydia, sent many rich and valuable presents to the oracle of Delphos, amongst which were six cups of gold, weighing thirty talents, and greatly esteemed for the workmanship. He made war upon Miletus and Smyrna, took the city of Colophon, and subdued the whole country of Troas. In his reign, and by his permission, the city of Abydus was built by the Milesians. Plutarch and other writers give a different account of his accession to the crown of Lydia, and inform us, without making any mention of the queen, that Gyges rebelled against Candaules, and slew him in an engagement. In Gyges commenced the third race called *Mermnadæ*, who were also, properly speaking, Heraclidæ, being descended from a son of Hercules by Omphale.

Gyges reigned thirty-eight years, and was succeeded on the throne by his son Ardyes. This prince carried on the war against the Milesians which his father had begun, and possessed himself of Priene, which in those days was a strong city. In his reign the Cimmerians invaded and overran all Asia Minor; but what battles were fought between the Lydians and these invaders, and with what success, we find nowhere mentioned. Herodotus only informs us, that in the time of Ardyes they possessed themselves of Sardis, the metropolis of Lydia, but that they failed to reduce the castle. Ardyes reigned forty-nine years, and was succeeded by his son Sadyattes, who reigned twelve years, during most part of which he carried on war with the Milesians.

After him came his son Alyattes, who for the space of five years continued the war which his father had begun against the Milesians, ravaging their country, and about harvest-time carrying away all their corn yearly, in order to oblige them, from want of provisions, to surrender their city, which he knew he could not reduce in any other way, the Milesians being at that time masters of the sea. In the twelfth year of this war the Lydians having set fire to the corn in the fields, the flames were carried by a violent wind, which happened at that time to blow, to the temple of Minerva at Assesus, and burned it down to the ground. Not long afterwards, Alyattes falling sick, sent to consult the oracle at Delphos; but the god refused to return any answer until the king should rebuild the temple of Minerva at Assesus. Alyattes, thus warned, despatched ambassadors to Miletus, enjoining them to conclude a truce with the Milesians until the temple should be rebuilt. On the arrival of the ambassadors, Thrasybulus, then king of Miletus, having commanded all the corn which was at that time in the city to be brought into the market-place, ordered the citizens to banquet in public, and to revel as if the city were plentifully stored with all manner of provisions. This stratagem Thrasybulus practised, that the ambassadors, seeing such quantities of corn, and the people everywhere diverting themselves, might acquaint their master with his affluence, and thus divert him from pursuing the war. As Thrasybulus had intended, so it happened. Alyattes, who believed the Milesians greatly distressed for provisions, receiving a different account from his ambassadors, changed the truce into a lasting peace, and ever afterwards lived in amity and friendship with Thrasybulus and the Milesians.

After a reign of fifty-seven years, he was succeeded by his son Crœsus, whose uninterrupted prosperity, in the first years of his reign, far eclipsed the glory of his predecessors. He was the first who made war on the Ephesians, whose city he besieged and took, notwithstanding their consecrating it to Diana, and fastening the walls by a rope to her temple, which was seven stadia distant from the city. After the reduction of Ephesus, he under various pretences attacked the Ionians and Æolians, obliging them, and all the other Greek states of Asia, to pay him an annual tribute. Having met with such extraordinary success by land, the Lydian prince determined to render his power equally conspicuous by sea. For this purpose he had serious thoughts of equipping a fleet, with which he purposed to invade and conquer the Grecian islands directly opposite to his dominions. But this design, which, considering the slow progress of maritime power amongst the nations most diligent in attaining it, would probably have failed of success, was prevented by the advice of a philosophical traveller, conveyed in such a lively turn of wit as easily changed the resolution of the king. Bias of Priene in Ionia (some say Pittacus of Mitylene in the isle of Lesbos), whilst he travelled, after the Grecian custom, from curiosity and a love of knowledge, was presented to Crœsus at the Lydian court; and being asked by that prince what news he brought from Greece, answered, with a republican freedom, that the islanders had collected powerful squadrons of cavalry with an intention of invading Lydia. "May the gods grant," said Crœsus, "that the Greeks, who are unacquainted with horsemanship, should attack the disciplined valour of the Lydian cavalry; there would speedily be an end to the contest." "In the same manner," replied Bias, "as if the Lydians, who are totally unexperienced in naval affairs, should invade the Grecians by sea." Struck by the acuteness of this unexpected observation, Crœsus desisted from his intended expedition against the islands; and, instead of employing new means for extending his conquests, determined peaceably to enjoy the laurels he had won, and to display the grandeur he had attained. But his happiness was soon afterwards allayed by the death of his favourite son Atys, who was unfortunately killed in the chase of a wild boar. This loss rendered him disconsolate for two years, and reduced him to a state of inaction, till the conquests of Cyrus, and the growing power of the Persians, roused up his martial spirit, and diverted his mind to other thoughts.

Crœsus apprehending that the success which had attended Cyrus in all his undertakings might at last prove dangerous to himself, resolved if possible to put a stop to his progress. In adopting this resolution, which might probably be attended with the most important consequences, he was desirous to learn the will of heaven concerning the issue of the war. The principal oracles which he consulted were those of Branchis in Ionia, of Ammon in Libya, and of Delphi in Greece. But, amongst these respected shrines, the oracle of Delphi maintained its ascendant, as the most faithful interpreter of fate. Crœsus was fully persuaded of its veracity; and, generously desirous to compensate the priests of Apollo for the trouble which he had already given, and still meant to give, he sacrificed three thousand oxen to the god, and adorned his shrine with gifts equally valuable for the workmanship and for the materials, viz. precious vessels of silver, ewers of iron beautifully inlaid and enamelled; various ornaments of pure gold, particularly a golden lion weighing ten talents, and a female figure three cubits or near five feet in height. In return for these magnificent presents, the oracle, in equivocal and ambiguous language, flattered Crœsus with obtaining an easy victory over his enemies, and with enjoying a long life and a prosperous reign. The god at the same time enjoined him to contract an alliance with the most powerful of the Grecian states.

Elevated with these favourable predictions of Apollo, Crœsus prepared to yield a ready obedience to the only condition required on his part for the accomplishment of his aspiring design. Not deeming himself sufficiently acquainted with the affairs of Greece to know what particular republic was meant by the oracle, he made especial inquiry of those who were best informed concerning the state of Europe, and discovered, that amongst all the members of the Grecian confederacy, the Athenians and Lacedæmonians were justly entitled to the pre-eminence. But in order to learn which of these communities deserved the epithet of "most powerful," it was necessary to send ambassadors into Greece. The Lydians despatched on this important commission soon discovered that the Athenians, having been long harassed by internal dissensions, were actually governed by the tyrant Pisistratus. The Spartans, on the other hand, though anciently the worst regulated of all the Grecian communities, had enjoyed domestic peace and foreign prosperity ever since they had adopted the wise institutions of Lycurgus. After that memorable period, they had repeatedly conquered the warlike Argives, triumphed over the hardy Arcadians, and, notwithstanding the heroic exploits of Aristomenes, subdued and enslaved their unfortunate rivals of Messene. To the Lydian ambassadors, therefore, the Spartan republic appeared to be pointed out by the oracle as the community whose alliance they were enjoined to solicit. Having accordingly repaired to Sparta, they were introduced not only to the kings and senate, but, as the importance of the negociation required, to the general assembly of the Lacedæmonians, to whom they, in few words, declared the object of their commission. "Lacedæmonians, we are sent by Crœsus, king of the Lydians and of many other nations, who being commanded by the oracle of Apollo to seek the friendship of the most powerful people of Greece, now summon you, who justly merit that epithet, to become his faithful allies, in obedience to the will of the god whose authority you acknowledge." The Lacedæmonians, pleased with the alliance of a warlike king, and still more with the fame of their valour, readily accepted the proposal. To the strict connection of an offensive and defensive league they joined the more respected ties of sacred hospitality. A few years before this transaction they had sent to Sardis to purchase gold for making a statue of Apollo, and on that occasion Crœsus had gratuitously supplied their wants. Remembering this generosity, they gave the Lydian ambassadors at their de-parture, as a present for their master, a vessel of brass containing three hundred amphoras (above twelve hogs-heads), and beautifully carved on the outside with various forms of animals.

Crœsus, having thus happily accomplished the design recommended by the oracle, was eager to set out upon his ntended expedition. He had formerly entered into alli-ances with Amasis king of Egypt, and Labynetus king of Babylon; and he had now obtained the friendship of the most warlike nation of Europe. The newly-raised power of Cyrus and the Persians seemed incapable of resisting uch a formidable confederacy. Elevated with these flat-ering ideas of his own invincible greatness, Crœsus wait-d not to attack the Persian dominions until he had col-ected the strength of his allies. The sanguine impetuosi-y of his temper, unexperienced in adversity, unfortunately recipitated him into measures no less daring than ruinous. Attended only by the arms of Lydia, and a numerous band f mercenaries, whom his immense wealth enabled him at ny time to call into his service, he marched towards the iver Halys, and, having with much difficulty crossed that eep and broad stream, entered the province of Cappado-ia, which formed the western frontier of the Median do-minions. That unfortunate country soon experienced all he calamities of invasion. The Pterian plain, the most eautiful and fertile district of Cappadocia, was laid waste; he ports of the Euxine, as well as several inland cities, were plundered, and the inoffensive inhabitants were either ut to the sword or dragged into captivity. Encouraged y the unresisting softness of the natives of those parts, Crœsus was eager to push forwards; and if Cyrus did not reviously meet him in the field, he had determined to pro-eed in triumph to the mountains of Persia. Against this angerous resolution he was in vain exhorted by a prudent ydian named Sandanis, who, when asked his opinion of he war, declared it with that freedom which the princes f the East have in every age permitted, amidst all the ride and caprices of despotic power, to men distinguished y the gifts of nature or education. "You are preparing," aid he, "to march against a people who lead a laborious nd a miserable life; whose daily subsistence is often de-ied them, and is always scanty and precarious; who drink nly water, and who are clothed with nothing but the skins f wild beasts. What can the Lydians gain by the conquest f Persia; the Lydians, who enjoy all the advantages of which the Persians are destitute? For my part, I deem it blessing of the gods that they have not excited the war-like poverty of these miserable barbarians to invade and plunder the luxurious wealth of Lydia." The moderation f this advice was rejected by the fatal presumption of Crœsus; confounding the dictates of experienced wisdom with the mean suggestions of pusillanimity, he dismissed he prudent counsellor with contempt, and prepared to pro-ecute his fatal enterprise.

Meanwhile, the approach of Cyrus, who was not of a temper to permit his dominions to be ravished with impu-ty, afforded the Lydian king an opportunity of bringing he war to a more speedy issue than by his intended ex-edition into Persia. The army of Cyrus gradually aug-ented as he advanced; the tributary princes cheerfully ontributing with their united strength towards the assis-ance of a master whose valour and generosity they ad-mired, and who now took arms to protect the safety of his ubjects, as well as to support the grandeur of his throne. Such was the rapidity of his movement, especially after being informed of the destructive ravages of the enemy in Cappadocia, that he marched from the shores of the Caspian to those of the Euxine Sea before the army of Crœsus had provided the necessaries for their advance. That prince, when apprized of the neighbourhood of the Persians, encamped on the Pterian plain; Cyrus likewise took up a position at no great distance; frequent skirmishes occurred between the light troops; and at length a general engagement was fought with equal fury and perseverance, and only terminated by the darkness of night. The loss on both sides prevented a renewal of the battle. But the numbers as well as the courage of the Persians much exceeded the expectation of Crœsus; and as they discovered no intention of harassing his retreat, he determined to fall back towards Sardis, in order to spend the winter in the amusements of his palace, and, after summoning his numerous allies to his standard, to take the field early in the spring with such increase of force as would be sufficient to overpower the Persians.

But this design was defeated by the watchful vigilance of Cyrus. That experienced leader allowed the enemy to retire without molestation, carefully informing himself of every movement they made, and of every measure they seemed determined to pursue. Patiently watching the opportunity of a just revenge, he waited until Crœsus had re-entered his capital, and disbanded the foreign mercenaries, who composed the most numerous division of his army. Cyrus then put his Persians in motion; and such was his celerity, that he brought the first intelligence of his own arrival in the plain of Sardis. Crœsus, whose firmness might well have been shaken by the imminence of this unforeseen danger, was not wanting on the present occasion to the duties which he owed to his fame and the lustre of the Lydian throne. Though his mercenaries were disbanded, his own subjects, who served him from attachment, who had been long accustomed to victory, and who were animated with a high sense of national honour, burned with a desire to check the daring insolence of the invaders. Crœsus indulged and encouraged this generous ardour. The Lydians in that age fought on horseback, armed with long spears; the strength of the Persians consisted in their infantry. The latter were so little accustomed to the use of horses, that camels were almost the only animals which they employed as beasts of burden. This circumstance suggested to a Mede, by name Harpagus, a stratagem, which, being communicated to Cyrus, was immediately adopted with the approbation of that prince. Harpagus, having observed that horses had a strong aversion to the shape and smell of camels, advised that the Persian army should be drawn up in the following order: All the camels which had been employed to carry baggage and provisions were collected into one body, and arranged in a line fronting the Lydian cavalry. The foot soldiers of the Persians were posted immediately behind this line, and placed at a due distance; and the Median horse, a few squadrons of which followed the standard of Cyrus, formed the rear of the army. As the troops on both sides approached to join battle, the Lydian cavalry, terrified at the unusual appearance of the camels, mounted with men in arms, were thrown into disorder, and the horses, turning their heads, endeavoured to escape from the field. Crœsus, who perceived the confusion, was ready to despair of his fortune; but the Lydians, abandoning their horses, prepared with uncommon bravery to attack the enemy on foot. Their courage deserved a better fate; but, unaccustomed as they were to this mode of fighting, they were received and repelled by the experienced valour of the Persian infantry, and obliged to take refuge within the fortified strength of Sardis, where they imagined themselves secure. The walls of that city bade defiance to the rude art of attack, as then practised by the most warlike nations. If the Persian army should invest it, the Lydians were provided with provisions for several years; and there was reason to expect that in a few months, nay even weeks, they would receive such assistance from Egypt, Babylonia, and Greece, to which countries they had already sent ambassadors, as would oblige the Persians to raise the siege.

The Lydian ministers despatched into Greece met with great sympathy from the Spartans. That people were particularly observant of the faith of treaties; and whilst they punished their enemies with unexampled severity, they behaved with generous compassion towards those whom they had once accepted as allies. They immediately resolved therefore to send speedy and effectual relief to Crœsus; and for this purpose they assembled their troops, made ready their vessels, and prepared every thing necessary for the expedition. The valour of the Spartans might perhaps have upheld the sinking empire of Lydia; but before their armament set sail, Crœsus was no longer a sovereign. Notwithstanding the strength of Sardis, that city had been taken by storm on the twentieth day of the siege; the walls having been scaled in a quarter which, appearing altogether inaccessible, was too carelessly guarded. This was effected by the enterprise of Hyreades, a Mede, who accidentally observed a sentinel descend part of the rock in order to recover his helmet. Hyreades was a native of the mountainous province of Mardia, and, being accustomed to clamber over the dangerous precipices of his native country, resolved to try his activity in passing the rock upon which he had discovered the Lydian. The design was more easily accomplished than he had reason to expect; emulation and success encouraged the bravest of the Persians to follow his example; these were supported by great numbers of their countrymen; the garrison of Sardis was surprised, the citadel stormed, and the rich capital of Lower Asia subjected to the vengeful rapacity of an indignant conqueror. Thus ended the ancient kingdom of Lydia, which continued subject to the Persians until they in their turn were conquered by the Macedonians.

LYDIAT, Thomas, a learned English divine, was born in 1572, and educated at Oxford. About the year 1609, he became acquainted with Dr James Usher, afterwards archbishop of Armagh, who carried him to Ireland. He studied at Dublin College for about two years, after which he returned to England; and the rectory of Alkrington becoming vacant, he was presented to it. But at length, being bound for the debts of a near relation, which he found himself unable to pay, having before spent his patrimony in printing several books, he was sent to prison, and confined at Oxford, in the King's Bench, and elsewhere, until Sir William Boswell, a generous patron of learned men, Dr Robert Pink, warden of New College, Bishop Usher, and Dr Laud, discharged the debt. In the civil wars he suffered much in his rectory of Alkrington from the parliamentary party, by whom he was four times pillaged to the value of at least L.70, and even forced for a quarter of a year together to subsist on the bounty of others. He wrote some pieces in English, and several works in Latin, on chronology, and natural history; and died in 1646.

LYDIUS Lapis, in the natural history of the ancients, the name of the stone used by way of touchstone for the trial of gold and silver, and called by some *Heraclius lapis*. Both of these names were also applied by the ancients to the loadstone; and hence has arisen no small misunderstanding of their works. Pliny has observed, that both the loadstone and touchstone were at times called *Lydius* and *Heraclius lapis*.

The true *lapis Lydius*, or touchstone, was anciently found only in the river Tmolus; but it was afterwards discovered in other places, and is now very common in many of the German rivers. The ancients give us very remarkable and circumstantial accounts of the uses they made of it; and it is plain that, by means of it, they were able to discern the alloys of gold with very great exactness. We at present use several different stones under this name, and for the same purpose. In Italy, a green marble called *verdello* is most frequently employed; and with us small pieces of *basalt*.

LYDNEY, a town of the county of Gloucester, in the hundred of Blideslow, on the western side of the Severn, 123 miles from London. It was formerly a Roman station, and more extensive than at present. The market was held on Wednesday, but has of late years disappeared. In the neighbourhood are extensive iron and coal mines. The parish, including the chapelry of Aylburton, contained a population amounting in 1801 to 1032, in 1811 to 1160, in 1821 to 1393, and in 1831 to 1534.

LYME-REGIS, a borough and market town of the county of Dorset, in the hundred of Whitchurch, 143 miles from London. It stands on the side of a steep hill, overlooking the sea, and has a small artificial harbour, called the Cobbe, secure for vessels of small tonnage. It has been much frequented of late years for the purposes of sea-bathing, and appropriate institutions for the accommodation of visitors have been established. It is an ancient borough, and previously to the passing of the reform act returned two members to parliament, but now elects only one. There is a well-supplied market on Friday. The population amounted in 1801 to 1451, in 1811 to 1925, in 1821 to 2269, and in 1831 to 2621.

LYMINGTON, a market and borough town of the county of Hants, in the parish of Boldre, in the New Forest. It stands on a creek about half a mile from the sea. It is pleasantly situated on the brow and declivity of a gentle hill, looking towards the Isle of Wight; and many of the houses are highly respectable in appearance. It has been lately frequented by visitors for the purpose of sea-bathing. It is a corporation, and returns, as before the recent law, two members to parliament; but other places in the vicinity are added to make up the proper constituency. The population amounted in 1801 to 2378, in 1811 to 2641, in 1821 to 3164, and in 1831 to 3361.

LYMPH, a fine colourless fluid, separated in the body from the mass of blood, and contained in peculiar vessels called *lymphatics*.

LYMPHÆA were artificial caves or grottoes amongst the Romans, furnished with a great many tubes, canals, and various hydraulic apparatus, through which the water gushed out unexpectedly upon the spectators whilst they were admiring the beautiful arrangement of the shell-work in the grotto.

LYMPHATI was a name given by the Romans to such as were seized with madness. It is supposed to be used for *Nymphati*, because the ancients imagined that every person who had the misfortune to see a nymph was instantly struck with frenzy. *Lymphati* may indeed signify madmen, as derived from *lympha*, water, over which element the nymphs were thought to preside; but it appears most likely that distracted people were called *lymphati*, from the circumstance of madmen being affected with the *hydrophobia*, or dread of water, after the bite of a mad dog; for this peculiarity, in cases of canine madness, was not unknown to the Romans.

LYNCEUS, in fabulous history, one of the fifty sons of Ægeus, married Hypermnestra, one of the fifty daughters of Danaus.

Lynceus, in fabulous history, one of the Argonauts who accompanied Jason in the expedition to Colchis to obtain the golden fleece. He was of great use to the Argonauts, by enabling them to avoid the sand-banks and rocks which they found in their way. The poets say that Lynceus had so piercing a sight that it could not only penetrate to the bottom of the sea, but even to the shades below. Some mythologists suppose that this fable arose from the skill of Lynceus in observing the stars, and discovering the mines of gold and silver concealed in the earth.

LYNCURIUM, a stone believed to be the same with the tourmaline. The name is derived from λυγξ, *lynx*, and ὀυϱον, *urine*.

LYNCURIUS Lapis, a stone which was supposed capable of producing mushrooms.

LYNDHURST, a township and chapelry in the parish of Minstead, in the county of Hampshire. It is situated in one of the most beautiful parts of the New Forest, nine miles from Southampton, and eighty-six from London. The forest is about forty miles in compass, containing several towns and villages, with thirty-six churches, and, though laid waste as a hunting ground by William the Conqueror, is in a great part now fertile and productive. The pleasing town of Lyndhurst may be considered as a kind of metropolis of the New Forest. It gives the title of a baron to a late lord chancellor. The inhabitants amounted in 1801 to 882, in 1811 to 1015, in 1821 to 1170, and in 1831 to 1236.

LYNN-REGIS, a sea-port, market-town, and borough of the county of Norfolk, in the hundred of Freebridge, ninety-seven miles from London. It is situated on the right bank of the river Ouse, about eight miles from the sea. The harbour is capable of receiving 300 sail of vessels. From its situation at the mouth of a long river, it is advantageously placed for exporting the productions of the soil, and for conveying to a large district the foreign commodities they require. There is a large quantity of wine imported from Portugal and Spain, and of hemp, wood, flax, and other articles from the Baltic. The market-place is very extensive and handsome; the quays for landing wine are convenient; and though some of the streets are narrow, it is on the whole a well-built town. It is governed by a mayor, high steward, recorder, and aldermen, and returns two members to parliament. There are good markets on Tuesdays and Saturdays. The principal church, St Margaret's, is one of the largest parochial churches in England. It was erected in 1160, and repaired and enlarged in 1741. There are two other churches or chapels, besides places of worship for the several descriptions of dissenters. The population amounted in 1801 to 10,096, in 1811 to 10,259, in 1821 to 12,253, and in 1831 to 13,370.

LYON King of Arms. This office is of great antiquity and respect in Scotland; and although the precise date of its institution is unknown, yet it must have been as early as the introduction of armorial figures as hereditary marks of gentility and distinction into this country, which was in the twelfth century. The regalia of this officer are, a crown of gold, with a crimson velvet cap, a gold tassel, and an ermine lining; a velvet robe reaching to his feet, with the arms of the kingdom embroidered thereon, before and behind, in the proper tinctures; a triple row of gold chains round his neck, with an oval gold medal pendant thereto, on one side of which is the royal bearing, and on the other St Andrew with his cross enamelled in proper colours, and a baton of gold enamelled green, powdered with the badges of the kingdom. The Lord Lyon's rank is superior to that of any other king of arms, as he holds his office immediately from the sovereign by commission under the great seal; whereas the kings at arms in England are deputies to the Earl Marshal, and act under his authority. Formerly Scotland was divided into two provinces, the one on the north, and the other on the south side of the Forth; and these provinces were under the management of two deputies appointed by the Lord Lyon, to superintend the execution of all the business of his office. Before the revolution, the Lord Lyon, upon his admission to office, was solemnly crowned by the sovereign or his commissioner, in presence of the nobility, the officers of state, and other great men, after a suitable sermon preached in the royal chapel; and his crown was of the same form with the imperial crown of the kingdom. On solemn occasions he wears the regalia above described; at all other times he wears the oval gold medal or badge on his breast, suspended by a broad green ribbon. He has the absolute disposal of all the offices in his own court, and of the places of heralds and pursuivants. The messengers at arms throughout Scotland are also created by him, and are amenable to his jurisdiction; and the powers vested in him by his commission are the same with those of the sovereign in all matters relative to the marks of gentility. See Heraldry.

LYONET, Peter, an ingenious naturalist, and member of several learned societies, was born at Maestricht, and descended from a very ancient and respectable family of Lorraine. He had scarcely attained his seventh year when he displayed an uncommon strength and agility in all bodily exercises; but he was not less diligent in the improvement of his mind. Being placed at the Latin school, he learned chronology, and exercised himself in Latin, Greek, and French poetry, as also in Hebrew, logic, and the Cartesian physics. He was particularly fond of the study of languages, of which he understood no less than nine, living and dead. Having entered the university of Leyden, he studied the Newtonian philosophy, geometry, and algebra; but his father, who was a clergyman, desiring that he should apply himself to divinity, he reluctantly abandoned the former studies, his passion for which was not to be easily overcome. At the same time he applied himself to anatomy, and also to music and drawing. He afterwards began to practise sculpture, and executed several pieces in wood, some of which are preserved, and have been greatly admired by the artists. He then betook himself to drawing portraits of his friends from life, in which, after three or four months' practice, he became a great proficient. Having attained the degree of candidate in divinity, he resolved to study law, to which he applied himself with so much zeal, that he was promoted at the end of the first year. Having arrived at the Hague, he undertook the study of deciphering, and became secretary of ciphers, translator of the Latin and French languages, and patent-master to their High Mightinesses. Meanwhile, having taken a strong liking to the study of insects, he undertook to give an historical description of such as are found about the Hague, and with that view collected materials for several volumes; and having invented a method of drawing adapted thereto, he enriched this work with a great number of plates, universally admired by all connoisseurs. In the year 1724 was printed, at the Hague, a French translation of a German work entitled the Theology of Insects, by Mr Lesser. Love of truth induced Mr Lyonet to defer the publication of his description above mentioned, and to make some observations on that work, to which he added two beautiful plates, engraved from his designs. This performance caused his merit to be universally known. The celebrated M. de Reaumur had this translation reprinted at Paris, not so much on account of the work itself, as of Mr Lyonet's observations; and bestowed upon it, as did also many other authors, the highest encomiums. He afterwards executed drawings of the fresh-water polypus for Mr Trembley's beautiful work, 1744. The ingenious Wandelaar had engraved the first five plates, when Mr Lyonet, who had never witnessed this operation, concerned at the difficulties he experienced in getting the remaining eight finished in the superior style he required, resolved to perform the task himself. He accordingly took a lesson of one hour from Mr Wandelaar, engraved three or four small plates, and immediately began upon the work himself, which he executed in such a manner as attracted the highest praise, both from Mr Trembley and from many other artists, particularly the celebrated Van Gool, who declared that the performance astonished not only the amateurs, but also the most experienced artists. In 1748 he was admitted a member of the Royal Society of London. In 1749 he began, by mere chance, his collection of horns and shells, which, according to the universal testimony of all travellers and amateurs who visited it, became the most beautiful, and certainly one of the most valuable, in Europe. In 1753 he was chosen a member of the Dutch Society of Sciences at Haerlem, then recently established; and in 1757, after the celebrated M. le Cat, professor of anatomy and surgery, had seen Mr Lyonet's *Traité Anatomique de la Chénille qui ronge le Bois de Saule*, with the drawings belonging to it (a work which was afterwards published), he was elected member of the Royal Academy of Sciences of Rome, of which M. le Cat was perpetual secretary. After the publication of this treatise, he became, in 1760, member of the Royal Academy of Sciences of Berlin; in 1761, of the Imperial Academy of Naturalists; and, in 1762, of the Imperial Academy of Sciences at St Petersburg. In order to enable such as might be desirous of following him in his intricate and astonishing discoveries respecting the structure of this animal, Mr Lyonet published, in the Transactions of the Dutch Society of Sciences at Haerlem, a description and plate (as he afterwards did in French at the beginning of his *Traité Anatomique*) of the instrument and tools he had invented for the purpose of dissection, and likewise of the method he had used to ascertain the degree of strength of his magnifying glasses. But notwithstanding all his labours, which were considerably increased by the extensive correspondence which he had for many years carried on with several learned persons, he still found means to set apart a large proportion of his time for the immediate service of his country; but he was not fortunate enough to get any other recompense for his exertions than sorrow and disappointment. During the last fifteen or twenty years of his life, Mr Lyonet added to the valuable treasure he had already collected of natural curiosities, a superb cabinet of paintings, consisting of more than 560 performances, amongst which are many of the most eminent works of the first Dutch masters. His object in doing so was to procure himself some amusement during the latter part of his life, when old age and infirmities had weakened his powers, and set bounds to his activity. He had always indeed accustomed himself to employment, insomuch that he wrote some pieces of Dutch poetry; and this disposition remained with him until within a fortnight of his death, when he was attacked with an inflammation in the chest, which, though apparently cured, proved in the end the cause of his death. He died at the Hague in January 1789, aged eighty-three years, leaving behind him a most estimable character.

LYONS, or Lyon, an arrondissement of the department of the Rhone, in France, 531 square miles in extent. It comprehends sixteen cantons, which are divided into 128 communes, and contains 225,670 inhabitants. The capital is the city of the same name, built by the Romans before the Christian era, and at present, next to Paris, the most important city in the French dominions. It is on a peninsula formed by the junction of the rivers Saone and Rhone; the quays on whose banks are the most striking parts of the city, which, though built since the revolutionary destruction of it, has scarcely any erections worthy of much admiration; but some of the numerous bridges over the two rivers are striking objects. The most remarkable buildings are the Saracenic cathedral, the hotel de ville, and the hospital called hotel de Dieu. There is an establishment for education, consisting of a primary and secondary school of great repute, with the finest provincial library in France, consisting of about 120,000 volumes, with which are connected a museum, an observatory, a botanical garden, and a veterinary institution. Abundance of Roman antiquities are to be seen in the city and its vicinity. The population is at present about 140,000 persons, but it includes the commune. The chief occupation is the manufacturing of silk goods, velvets, satins, and all other kinds of the same elegant fabrication. There are, besides, as appears by the statement below, manufacturers of cotton, woollen, and leather goods, as well as of gold lace, jewellery, paper, and a variety of chemical preparations, and of perfumery. Lyons is remarkable as the birth-place of the Emperors Claudius and Caracalla, and of the poet Sidonius Apollinaris; and, in modern times, of the sculptor Coisevor, of the naturalist Jussieu, and of the antiquarian Spon. It is in long. 4. 44. E., and lat. 45. 45. N.

A Statement of the Operative Population of the City of Lyons, distinguishing the several Trades and Manufactures in which the same are engaged, and the number actually employed in each, exclusively of their Families when the same are not employed in any Trade or Manufacture.

The quantity of silk manufactured during the year 1835, was 743,125 kilogrammes. The returns show an excess of 24,422 kilogrammes over the quantity of 1833, and 141,516 kilogrammes over that of 1824, which latter was the most prosperous year during the restoration. The kilogramme is equal to 2 lbs. 8 oz. 3 dwts. 2 grs. troy weight.

LYRA, in *Astronomy,* a constellation in the northern hemisphere. The number of its stars, in Ptolemy's catalogue, is ten; in Tycho's eleven; in Hevelius's seventeen; and in the Britannic catalogue twenty-one.

LYRE, a musical instrument of the stringed kind, much used by the ancients. Concerning the number of strings with which this instrument was furnished, there has been great controversy. Some assert that it had only three; that the sounds of the two remote were acute, and that of the intermediate one a mean between these two extremes; and that Mercury, the inventor, compared these three chords to as many seasons of the year, which were all that the Greeks reckoned, namely, summer, winter, and spring, assigning the acute to the first, the grave to the second, and the mean to the third. Others assert that the lyre had four strings; that the interval between the first and the fourth was an octave; that the second was a fourth from the first, and the fourth the same distance from the third, and that from the second to the third was a tone. Another class of writers contend that the lyre of Mercury had seven strings. Nicomachus, a follower of Pythagoras, and the chief of them, gives the following account of the matter: "The lyre made of the shell was invented by Mercury; and the knowledge of it, as it was constructed by him of seven strings, was transmitted to Orpheus; Orpheus taught the use of it to Thamyris and Linus; the latter of whom taught it to Hercules, who communicated it to Amphion the Theban, who built the seven gates of Thebes to the seven strings of the lyre." The same author proceeds to relate, "that Orpheus was afterwards killed by the Thracian women; that they are reported to have cast his lyre into the sea, which was afterwards thrown up at Antissa, a city of Lesbos; that certain fishers finding it, brought it to Terpander, who carried it into Egypt, exquisitely improved, and, showing it to the Egyptian priests, assumed to himself the honour of its invention." This difference amongst authors seems to have arisen from their confounding together the Egyptian Thoth or Hermes, and the Greek Mercury. The invention of the primitive lyre with three strings was due to Hermes the Egyptian. The lyre attributed to the Greek Mercury is described by almost all the poets as an instrument of seven strings. Vincenzio Galilei has collected the various opinions of the Greek writers who have mentioned the invention of the *chelys* or *testudo;* and Mr Spence did the same thing in a very circumstantial but ludicrous manner. "Horace talks of Mercury as a wonderful musician, and represents him with a lyre. There is a ridiculous old legend relating to this invention, which informs us, that Mercury, after stealing some bulls from Apollo, retired to a secret grotto which he used to frequent, at the foot of a mountain in Arcadia. Just as he was going in, he found a tortoise feeding at the entrance of his cave; he killed the poor creature, and perhaps ate the flesh of it. As he was diverting himself with the shell, he was mightily pleased with the noise it gave from its concave figure. He had possibly been cunning enough to find out, that a thong pulled strait and fastened at each end, when struck with the finger, made a sort of musical sound. However that was, he went immediately to work, and cut several thongs out of the hides he had lately stolen, and fastened them as tight as he could to the shell of this tortoise; and, in playing with them, made a new kind of music with them, to divert himself in his retreat." This, considered only as an account of the first invention of the lyre, is not altogether unnatural. The most ancient representations of this instrument agree very well with the account of its invention. The lyre in particular on the old celestial globes was represented as made of one entire shell of a tortoise; and that of Amphion in the celebrated group of the Dirce or Toro, in the Farnese palace at Rome, which is of Greek sculpture, and very high antiquity, is figured in the same manner. There have, however, been many other claimants to the invention of the seven-stringed lyre. For though Mercury invented this instrument in the manner already related, it is said he afterwards gave it to Apollo, who was the first that played upon it with method, and made it the constant companion of poetry. According to Homer's account of this transaction, in his hymn to Mercury, it was given by that god to Apollo, as a peace-offering and indemnification for the oxen which Mercury had stolen from him. Diodorus informs us, that Apollo soon repenting of the cruelty with which he had treated Marsyas in consequence of their musical contest, broke the strings of the lyre, and by that means put a stop for a time to any further progress in the practice of the new instrument. "The Muses," adds he, "afterwards added to this instrument the string called *mese;* Linus, that of *lichanos;* and Orpheus and Thamyris, those strings which are named *hypate* and *parhypate.* Again, many ancient and cre-

Lyric Poetry || Lysias.

dible authors inform us, that, before the time of Terpander, the Grecian lyre had only four strings; and, if we may believe Suidas, it remained in this state 856 years, from the time of Amphion, until Terpander added to it three new strings, which extended the musical scale to a heptachord, or seventh, and supplied the player with two conjoint tetrachords. It was about 150 years after this period, that Pythagoras is said to have added an eighth string to the lyre, in order to complete the octave, which consisted of two disjoint tetrachords. But Boetius gives a different history of the scale, and informs us, that the system did not long remain in such narrow limits as a tetrachord. Choræbus, the son of Athis, or Atys, king of Lydia, added a fifth string; Hyagnis, a sixth; Terpander, a seventh; and at length Lychaon of Samos, an eighth. But all these accounts are irreconcileable with Homer's hymn to Mercury, where the *chelys* or *testudo*, the invention of which he ascribes to that god, is said to have had seven strings. There are many claimants amongst the musicians of ancient Greece to the strings afterwards added to these, by which the scale, in the time of Aristoxenus, was extended to two octaves. Athenæus more than once speaks of the nine-stringed instrument; and Ion of Chios, a tragic and lyric poet and a philosopher, who first recited his pieces in the eighty-second Olympiad, 452 B. C. mentions, in some verses quoted by Euclid, the ten-stringed lyre; a proof that the third conjoint tetrachord was added to the scale in his time, which was about fifty years after Pythagoras is supposed to have constructed the octachord. The different claimants amongst the Greeks to the same musical discoveries, only prove that music was cultivated in different countries, and that the inhabitants of each country invented and improved their own instruments; some of which happening to resemble those of other parts of Greece, rendered it difficult for historians to avoid attributing the same invention to different persons. Thus the single flute was ascribed to Minerva and to Marsyas; the syrinx or fistula, to Pan and to Cybele; and the lyre or cithara, to Mercury, Apollo, Amphion, Linus, and Orpheus. Indeed, the mere addition of a string or two to an instrument without a neck was so obvious and easy, that it is scarcely possible not to conceive that many people may have done it at the same time.

LYRIC POETRY was such as the ancients sung to the lyre or harp. It was originally employed in celebrating the praises of gods and heroes, and its characteristic was sweetness. The author or inventor of it is, however, unknown. It was much cultivated by the Greeks; and Horace was the first who attempted it in the Latin language. Anacreon, Alcæus, Stesichorus, Sappho, and Horace, were the most celebrated lyric poets of antiquity.

LYRODI, amongst the ancients, a kind of musicians who played on the lyre, and at the same time sung. This appellation was also given to such as made it their employment to sing lyric poems composed by others.

LYSANDRIA, a Samian festival, which was celebrated with games and sacrifices in honour of the Lacedæmonian general Lysander. It was anciently called *Herea;* but this name the Samians abolished by a public decree.

LYSIARCH, an ancient magistrate, who superintended the sacred games, and presided in matters of religion, in the province of Lycia. He was created in a council consisting of deputies from all the provincial cities, twenty-three in number. The lysiarchs were heads both of the council and the pontiffs of the province.

LYSIAS, one of the most celebrated of the Greek orators, was born at Athens 458 B. C., and died, at the age of eighty, B. C. 378. He was the contemporary of some of the greatest men that Athens ever produced, of Thucydides and Xenophon, of Euripides and Sophocles. He was the son of Cephalus, a Syracusan, and is himself sometimes said to have been a native of this city; but he was born at Athens, whither his father was induced to emigrate by the advice of his friend Pericles. Cephalus was distinguished both for his great riches and for his virtues. It was at his house that Plato placed the scene of the most celebrated of his works, his Dialogues on the Republic. Cephalus no doubt procured the best masters to forward the education of his son; but Lysias left Athens at a very early age (B. C. 443), and proceeded to Thurium in the south of Italy, to which place the Athenians were sending a colony. He was accompanied by the two celebrated historians Herodotus and Thucydides, and remained there for many years, during which time he is said to have studied the art of eloquence under two Syracusans, Tisias and Nisias. After the unsuccessful expedition of the Athenians to Sicily (B. C. 413), it would appear that Thurium, with their other dependencies in Magna Græcia, refused to submit any longer to Athenian supremacy. All those who remained well affected towards the parent state were obliged to fly, and Lysias on that occasion (B. C. 411) returned with his brother Polemarchus to Athens. Here he employed himself in commercial pursuits, and we are told that the two brothers employed one hundred and twenty slaves in the manufacture of shields. We do not hear that he took any active part in the stormy politics of Athens, now approaching the conclusion of her war with Sparta. Athens fell into the hands of Lysander, and thirty tyrants were appointed to administer the affairs of the city. The patriotism and riches of Polemarchus and of his brother Lysias marked them out as fit objects for persecution to the tyrants. Polemarchus was put to death, and Lysias with great difficulty saved his life by flying to Megara (B. C. 404). Here he engaged in the conspiracy to restore the independence of his country, and is said to have furnished three hundred men at his own expense to assist Thrasybulus. The tyrants were expelled, and Lysias returned to Athens (B. C. 403), where he commenced his new career as an orator. It does not appear that he was much employed in the assemblies of the people, but that he confined himself principally to writing *accusations* or *defences*, at the desire of such persons as had occasion to impeach the conduct of others, or to defend their own. As a reward for his services, Thrasybulus proposed to the people that he should be admitted to the freedom of the state; but Archinus procured its rejection, because the proposal had not been made first to the senate, as the law required. Plutarch states that there were extant in his time no less than 475 orations ascribed to Lysias, of which only 235 were genuine, according to Dionysius. We are likewise told that he composed institutions of oratory, epistles, and panegyrics; but of all these writings only thirty-four orations have come down to us, some of which are in an imperfect state. The pleadings of Lysias contain a curious detail of the domestic manners and internal economy of the Greeks. Dionysius of Halicarnassus has written a critique on the works and style of Lysias; and, according to him, the orator was particularly distinguished for simplicity and precision, as well as for the fidelity with which he depicted the manners of the age. Quintilian compares him to a clear and pure rivulet rather than to a majestic river, whilst Cicero considers him as the model of a perfect orator. The earliest edition of the orations of Lysias is that of Aldus, 1513; but the best is that of Taylor, Gr. et Lat. London, 1739, and of Reiske, Leipzig, 1772. The latest edition is by Foertoch (Lips. 1829); and he has also published separately, *Observationes criticæ in Lysiæ Orationes*, Lips. 1829. See also Franzius, *Dissertatio inaug. de Lysia oratore Attico-Græce scripta*, Norimb. 1828. There is an English translation of the Orations by Gillies, London, 1778.

LYSIMACHUS, one of the generals of Alexander, was son of Agathocles, one of the king's body guard, but of noble descent. He appears to have been one of the noblest characters that the age of Alexander, so fertile in great men, produced. He was the pupil of the philosopher Callisthenes, who attended Alexander in his expedition; and when the king ordered Callisthenes to be put to death for some slight offence, by the most cruel tortures, Lysimachus enabled his friend to escape by furnishing him with poison. (See CALLISTHENES.) It might have been expected that Alexander would have admired such conduct, but it was far otherwise. He ordered Lysimachus to be exposed to the fury of a lion, and that he should suffer a death somewhat resembling that which had been intended for his friend. The bravery of Lysimachus saved him: wrapping his cloak round his arm, he pushed it into the throat of the lion, and laid it dead at his feet. Alexander forgave him, and attached him more particularly to his own person. This story, which is told by Justin (xv. 3), Pliny (viii. 16), and Seneca (*De Ira*, 3, 17, et *De Clem.* 1, 25), is called fabulous by Curtius (viii. 1, 22), and is said to have originated from the circumstance of Lysimachus having been attacked by a lion in the forests of Syria, and having killed it without assistance. From this moment Alexander treated Lysimachus as his friend, and was so fond of him, that having accidentally wounded him on the forehead as he was dismounting, he took off his diadem and bound up his head with his own hands, presaging, as Justin remarks, the royal rank to which he would afterwards attain. History is then silent respecting Lysimachus till the death of Alexander (B. C. 323), when we find him receiving, as his share of the kingdom, Thrace, and the countries placed along the coast of the Euxine (Justin, xiii. 4). But Seuthes occupied Thrace with a powerful army, and it was found necessary to conquer him before he could take possession of the kingdom. In this he was successful, and also in repressing a rebellion which had broken out at Callatia, on the coast of the Black Sea (Diodor. xviii. 14; xix. 73). No sooner did he feel secure of his dominions, however, than he began to attack the Odrysæ, Getæ, and other nations around; but he was defeated and taken prisoner, according to some historians, though, according to others, it was his son. Be this as it may, his daughter was given in marriage to the king of the country for releasing the captive (Pausan. i. ix.). The ambition of Antigonus began to alarm the other successors of Alexander, and a league was entered into by Ptolemy, Cassander, and Lysimachus, to reduce his power within due bounds. The war was carried on with various success for several years. Lysimachus proceeded to Asia (B. C. 302) to attack Antigonus, who was then at Antigonea in Syria, and in his passage subdued Phrygia, Lydia, and other districts, taking possession of many strong fortresses, where Antigonus had collected much treasure. He was joined by Seleucus, who arrived from Babylon with a considerable body of troops, and a decisive battle was fought (B. C. 301) at Ipsus, where Antigonus was defeated and killed (Justin, xv. 4). In addition to Thrace, Lysimachus obtained Bithynia, and some countries along the Hellespont. Yet Demetrius, son of Antigonus, did not lose courage, but made constant attempts to recover his dominions. A league was formed against him by Lysimachus and Pyrrhus king of Epirus, and he was driven from the greater part of Macedonia; but the two allies afterwards disagreed, and Pyrrhus having been defeated, Lysimachus assumed the title of king of Macedonia, B. C. 286. In his latter years he put to death his son Agathocles, at the suggestion of his second wife, who was afraid that she herself and her children would fall into the hands of Agathocles on the death of Lysimachus. Seleucus, taking advantage of the odium which this act brought upon him, attacked Lysimachus, and having given him battle, Lysimachus was killed, B. C. 281 (Pausan. i. x.; Justin, xvii. 1, 2).

LYSIPPUS, a celebrated Greek statuary, of the city of Sicyon, in the Peloponnesus, flourished about 324 B. C. He was at first a worker in brass, but afterwards devoted himself to statuary, studying nature, by the advice of Eupompus, rather than following the manner of any master. He excelled all those who had preceded him, in the nicety of individual parts, and more particularly in the beauty of the hair. He lessened the size of the head, which had been exaggerated by the ancient sculptors, and made the body more slim, so as to increase the appearance of the height. He used to say, that former sculptors represented men as they should be, whilst he merely made them as they seemed to be. His reputation was such that his name was included in the famous edict published by Alexander, when he conferred on Apelles the sole right of painting his form, on Lysippus that of executing it in bronze, and on Pyrgoteles that of engraving it on precious stones. He is said (Plin. xxxiv. 7) to have produced fifteen hundred works of art, any one of which was sufficient to stamp him as a man of talent. Of these we can only mention a few of the most celebrated. There was one at Rome, the removal of which from the baths of Agrippa to the palace of the emperor, by order of Tiberius, had nearly caused a sedition. The populace clamoured for its being replaced, and Tiberius did not deem it prudent to deny their request. It was a statue called Apoxyomenos, representing, as its name implies, a man scraping himself in the bath with a strigilis, an instrument to clean the body of the particles of sweat. He executed many statues of Alexander, representing him at different periods of his life; and he so managed, that a slight bend of the head, for which Alexander was remarkable, became rather a beauty than a deformity. One of these statues was so much admired by Nero, that he caused it to be covered with gold, to the great grief of all true lovers of the art of sculpture. He executed a very fine bronze statue of Cupid with a bow, for the inhabitants of Thespis; also equestrian statues of twenty-five Macedonians who fell at the passage of the Granicus, and which Metellus caused to be transported to Rome. It has been supposed, though without any clear proof, that the celebrated horses of Venice formed part of this group. There is a statue of Hercules in the Palazzo Pitti at Florence, which bears his name, and has in every respect a strong resemblance to the Farnese Hercules, excepting the position of the legs (*Mus. Pio-Clem.* iii. p. 66). This likewise has made it be supposed that the statue of the Palazzo Pitti is a copy of the Hercules of Lysippus, and that the Farnese is an imitation, on which Glycon thought he might engrave his name, on account of the change he had made in its position. Lysippus had as pupils his own sons, Dahippus, Bedas, and Euthycrates (Plin. xxxiv. 8. See Müller, *Handbuch der Archæologie der Kunst*, Breslau, 1830).

LYTTELTON, EDWARD, Lord Lyttelton, keeper of the great seal in the reign of Charles I. was eminent for his probity and moderation at the commencement of that monarch's disputes with his subjects. Without forfeiting his fidelity to the king, he preserved the esteem of the parliament until the year 1644, when he was made colonel of a regiment in the king's army at York. He died in 1645. Besides several of his speeches, which have been printed, he wrote reports in the Common Pleas and Exchequer, printed at London in 1683, in folio; several arguments and discourses; and various other things.

LYTTELTON, *George Lord*, eldest son of Sir Thomas Lyttelton, descended from the great Judge Lyttelton, was born in 1700, at seven months. The midwife, supposing him to be dead, threw him carelessly into the cradle, where, had not some signs of life been noticed by one of the attendants, he might never have recovered. He received the elements of his education at Eton school, where he showed an early inclination to poetry. His pastorals and some other light pieces were originally written in that seminary of learning. He was removed from thence to the university of Oxford, where he pursued his classical studies with uncommon avidity, and sketched the plan of his *Persian Letters;* a work which afterwards procured him great reputation, not only from the elegance of the language in which the letters were composed, but from the excellent observations they contained on the manners of mankind.

In the year 1728, he set out on the tour of Europe; and, upon his arrival at Paris, accidentally became acquainted with the Honourable Mr Poyntz, then our minister at the court of Versailles, who was so much struck with the extraordinary capacity of the young traveller, that he invited him to his house, and employed him in many political negociations, which he executed with great judgment and fidelity.

Mr Lyttelton's excellent conduct whilst on his travels was a lesson of instruction to the rest of his countrymen. Instead of lounging away his hours at the coffee-houses frequented by the English, and adopting the fashionable follies and vices of France and Italy, his time was passed alternately in his library and in the society of men of rank and literature. In this early part of his life, he wrote a poetical epistle to Dr Ayscough, and another to Mr Pope, both evincing singular taste and correctness.

After continuing a considerable time at Paris with Mr Poyntz, who, to use his own words, behaved like a second father to him, he proceeded to Lyons and Geneva; and thence went to Turin, where he was honoured with flattering marks of attention by his Sardinian majesty. He then visited Milan, Venice, and Genoa, and finally established himself at Rome, where he applied himself closely to the study of the fine arts, and, even in that celebrated metropolis, was allowed to be a perfect judge of painting, sculpture, and architecture.

During his continuance abroad, he constantly corresponded with his father, Sir Thomas Lyttelton. Several of his letters yet remain, and place his filial affection in a very distinguished light. He soon afterwards returned to his native country, and being elected representative for the burgh of Ockhampton in Devonshire, he conducted himself so much to the satisfaction of his constituents, that they several times re-elected him for the same place, without putting him to the least expense.

About this period, he received great marks of friendship from Frederick prince of Wales, and was, in the year 1737, appointed principal secretary to his royal highness, and continued in the strictest intimacy with him till the time of his death. In the year 1742, he married Lucy, the daughter of Mr Hugh Fortescue of Filleigh, in the county of Devon; a lady whose exemplary conduct, and uniform practice of religion and virtue, established his conjugal happiness upon the most solid basis.

In 1744, he was appointed one of the lords commissioners of the Treasury; and, during his continuance in that station, constantly exerted his influence in rewarding merit and ability. He was the friend and patron of Fielding, Thomson, Mallet, Young, Hammond, West, Pope, and Voltaire. On the death of Thomson, who left his affairs in a very embarrassed condition, Mr Lyttelton took that poet's sister under his protection. He revised the tragedy of Coriolanus, to which that writer had not put the last hand; and brought it out at the theatre-royal, Covent Garden, with a prologue of his own composition, in which he so affectingly lamented the loss of that delightful bard, that not only Mr Quin, who spoke the lines, but almost the whole audience, spontaneously burst into tears.

In the beginning of the year 1746, his felicity was interrupted by the loss of his wife, who died in the twenty-ninth year of her age, leaving him a son and daughter. He wrote a monody on her death, which will be remembered whilst conjugal affection and a taste for poetry exist in this country.

His masterly observations on the conversion and apostleship of St Paul were written at the desire of Mr Gilbert West, in consequence of Mr Lyttelton's asserting, that besides all the proofs of the Christian religion which might be drawn from the prophecies of the Old Testament, from the necessary connection it has with the whole system of the Jewish religion, from the miracles of Christ, and from the evidence given of his resurrection by all the other apostles, he thought the conversion of St Paul alone, duly considered, was of itself a demonstration sufficient to prove that Christianity was a divine revelation. Mr West was struck with the thought, and assured his friend, that so compendious a proof would be of great use to convince those unbelievers who would not attend to a longer series of arguments; and time has shown that he was not mistaken in his conjecture, as the tract is esteemed one of the best defences of Christianity which has hitherto been published.

In 1754, he resigned his office of lord of the Treasury, and was made cofferer to his majesty's household, and sworn a member of the privy council; previously to which, he married a second time, Elizabeth, daughter of Field-marshal Sir Robert Rich, a lady whose indiscreet conduct gave him great uneasiness, and from whom he was separated, by mutual consent, a few years after his marriage.

After being appointed chancellor, and under-treasurer of the court of exchequer, he was, by letters-patent dated the 19th of November 1757 (31 Geo. II.), created a peer of Great Britain, by the style and title of Lord Lyttelton, baron of Frankley, in the county of Worcester. His speeches on the Scotch and mutiny bills in the year 1747, on the Jewish bill in 1753, and on the privilege of parliament in 1763, showed sound judgment, powerful eloquence, and inflexible integrity. During the last ten years he lived chiefly in retirement, in the continual exercise of all the virtues which ennoble private life. His last work was *Dialogues of the Dead*, in which the morality of Fénélon and the spirit of Fontenelle are happily united.

In the middle of July 1773, he was suddenly seized with an inflammation of the bowels, which terminated in his death, at his seat near Hagley, on the 22d of that month. A complete collection of his works was published after his decease, by his nephew, Mr George Ayscough.

M.

Macaire || Macao.

M, A liquid consonant, and the twelfth letter in the alphabet. It has one unvaried sound, and is pronounced by striking the upper lip against the lower. In this the pronunciation of the letter *m* agrees with that of *b*, the only difference between the two consisting in a little motion made in the nose in pronouncing *m*, and not in *b;* and hence it happens that those who have taken cold, ordinarily pronounce *m* for *b*, the nose in that case being disabled from making the necessary motion. All consonants are formed with the aid of vowels; but in *m* the vowel precedes (*em*), in *b* it follows (*be*), and *m* is never mute. Quintilian observes, that the *m* sometimes ends Latin words, but never Greek ones; the Greeks in that case always changing it into *n*, for the sake of the euphony. M is also a numeral letter, and amongst the ancients it was used for a thousand; according to the verse,

M caput est numeri, quem scimus mille teneri.

When a dash is added on the top of it, as $\overline{\text{M}}$, it signifies a thousand times a thousand, or a million. M, as an abbreviation, stands for Manlius, Marcus, Martius, and Mucius; M. A. signifies *magister artium*, or master of arts; MS, manuscript, and MSS, manuscripts. M, in astronomical tables, and other things of that kind, is used for *meridional* or southern, and sometimes for *meridies* or mid-day. M, in medicinal prescription, is frequently used to signify a maniple or handful; and it is sometimes also put at the end of a recipe, for *misce*, mingle, or for *mixtura*, a mixture; thus, *m. f. julapium*, signifies mix and make a julep. M, in *law*, is the brand or stigma of a person convicted of manslaughter, and admitted to the benefit of his clergy.

MAAT, John. See Blankof.

MABILLON, John, a learned writer of France in the seventeenth century, was born at Perremonte, on the frontiers of Champagne, in the year 1632. He was educated in the university of Rheims, and afterwards entered into the abbey of the Benedictines of St Rémy. In the year 1663 he was appointed keeper of the treasures and monuments of France at St Denis; but having unfortunately broken a looking-glass, which was alleged to have belonged to Virgil, he desired leave of his superiors to quit an employment which frequently obliged him to say things he did not believe. Next year he went to Paris, and proved very serviceable to Father d'Acheri, who was desirous of having some young monk who could assist him in compiling his *Spicilegium*. This made Mabillon known. Soon afterwards the congregation of Saint-Maur having formed a design of publishing new editions of the Fathers, revised from the manuscripts in the libraries of the Benedictines, Mabillon was charged with the edition of St Bernard, which he prepared with extraordinary diligence. After this he published many other works evincing great capacity and industry. In 1682, he was employed by M. Colbert in examining some ancient titles relating to the royal family. In the year following the same minister sent him into Germany, to search the archives and libraries of the ancient abbeys, for all that seemed calculated to illustrate the history of the church in general, and that of France in particular. Mabillon published an account of this journey. In the year 1685 he undertook another journey into Italy, by order of the king of France, and returned the year following with a very noble collection. He placed in the king's library above three thousand volumes of rare books, printed and in manuscript, and composed two volumes respecting the pieces which he had discovered in that country. He was highly esteemed for his virtues as well as his learning.

MACAIRE, a town of France, in the department of the Gironde and arrondissement of Réolle, situated on the right bank of the Garonne, where the tide ceases to operate on that stream. It contains 1530 inhabitants.

MACAO, an island and town of China, belonging to the Portuguese, and the only European settlement within the limits of that empire. It was in consequence of the aid afforded by the Portuguese to the Chinese against the pirates who infested their coasts, that the privilege of a settlement was conceded to them. At first the Chinese refused to trade with the Portuguese; but being forced to have recourse to their aid, and having by their means compelled the pirates to raise the siege of Canton, and pursued them to Macao, which they took, most of the marauders were put to death. This service being reported to the emperor, he published an edict, by which the Portuguese were to have possession of Macao, with the power of forming a settlement, which they gladly accepted. They accordingly made choice of a peninsula, where they built a town, and fortified it after the European manner; but the Chinese have effectually provided for their own security, by not allowing them any provisions except what they receive through themselves. The peninsula on which the town is built is connected with the mainland by a neck of land not more than 100 yards in breadth. The territory attached to it is about three miles in length, and half a mile in breadth. The isthmus connecting it with the rest of the island is crossed by a wall projecting on both sides into the sea, and there the Chinese keep a gate and guardhouse. Beyond this wall the Portuguese are seldom permitted to pass, so that their communications with the continent are entirely in the power of the Chinese. Still the possession of the place was of great service to the Portuguese, who carried on a lucrative commerce with Japan, by which Macao became one of the richest places in their possessions. But since their expulsion from Japan, and the other European nations shared in the Canton trade, the place no longer enjoys its former prosperity.

The city of Macao is of considerable extent, the houses being built of stone, and constructed on the European plan, but without any attempt at exterior elegance, and the streets narrow and irregular. The public buildings consist of churches, convents, and the senate-house; the latter terminates the only spacious and level street of the town. The governor's house is situated on the beach, and near it is the English factory, a plain commodious building. The harbour has not a sufficient depth for vessels of great burden; and large ships generally anchor about six or seven miles off the town, bearing west-north-west. It is defended by several forts mounted with heavy cannon, and garrisoned by Portuguese troops. There is a Portuguese custom-house and quay on the south side of the town, where all ships, as they come into the bay, are obliged to send their boats. The Chinese treat the Portuguese with great *hauteur*, exacting duties sometimes in the port, and punishing individuals under the Portuguese regime; and the moment any resistance is made, the supply of provisions is stopped until harmony be restored. All sorts of provisions, vegetables, and fruits are found at Macao in great abundance. Long. 113. 32. E. Lat. 22. 10. N.

MACARCA, a market-town of the Austrian province of Dalmatia. It is a sea-port on the Adriatic, with a small but good harbour, which is protected from the winds by the islands Lessina and Brassa, opposite to it. The inhabitants are 1620, chiefly employed in the fisheries.

MACARIANS, in *Ecclesiastical History*, the followers of Macarius, an Egyptian monk, who, towards the close of the fourth century, was distinguished for his sanctity and virtue. In his writings there are some superstitious tenets, and also certain opinions which seem tainted with Origenism. The name has also been applied to those who adopted the sentiments of Macarius, a native of Ireland, who about the close of the ninth century propagated in France the error afterwards maintained by Averrocs, that one individual intelligence or soul performed the spiritual and rational functions in all the human race.

MACARONIC, a kind of burlesque poetry, consisting of a jumble of different languages, with words of the vulgar tongue Latinized, and Latin words modernized. *Macaroni*, amongst the Italians, as has been observed by Cælius Rhodiginus, signifies *a coarse clownish man;* and because this kind of poetry is patched up out of several languages, and full of extravagant words and combinations, the Italians, amongst whom it took its rise, gave it the name of *macaronic* poetry. Others, however, derive the name *a macaronibus*, from *macaroons*, a kind of confection made of meal not boulted, sweet almonds, sugar, and the white of eggs, and accounted a great dainty amongst the country people in Italy; which circumstance occasioned this kind of poetry, which consists of Latin, Italian, Spanish, French, English, and other languages, and is thus composed of various ingredients, to be called by the same name or appellation. Thus a bold fellow, in the *macaronic* style, says,

> Enfilavi omnes scadrones et regimandos.

And the following is in the same vein;

> Archelos pistoliferos furiamque manantum,
> Et grandem esmeutam quæ inopinum facta ruelle est:
> Toxinumque alto troublantem corda clochero, &c.

Theophilus Folengius, a Benedictine monk of Mantua, was the first who invented, or at least cultivated, this kind of verse. The best pieces of the Macaronic kind are, the *Baldus* of Folengio, and *Macaronis Forza* by Stefonio, a Jesuit, amongst the Italians; and the *Reatus veritabilis, super terribili esmeuta Paisanarum de Ruellis*, amongst the French. The famous Rabelais first transferred the *macaronic* style out of Italian verse into French prose, and upon this model formed some of the best things in his *Pantagruel.* We have but little in English in the *macaronic* style; and nothing scarce, excepting some little loose pieces collected in Camden's remains. But the Germans and people of the Netherlands have had their macaronic poets; for instance, the *Certamen Catholicum cum Calvinistis* of Martinius Hamconius Frisius, which contains about 1200 verses, all the words of which begin with the letter C.

MACASSAR, the chief settlement of the Dutch in the island of Celebes, named by them first Rotterdam, and situated on the south-west coast of the island. The fort is about half a mile from the beach, opposite to the road, where a pier extends which serves for unloading the ships, and close to which there are fifteen or sixteen feet of water. The walls of the fort are high and strong, being built of rock stone. Without is a large plain, on the north side of which is situated the town, where most of the Europeans reside. The Chinese live all together in one street, which is named after them. The Portuguese obtained permission to establish themselves here in 1525; but they were expelled by the Dutch in 1660, who hold the first and surrounding district in consequence of a treaty entered into with the native prince. The English in 1815 established a factory, which, however, they were soon under the necessity of abandoning. Numerous Chinese are settled here, who carry on a considerable trade with their native country. Macassar was formerly an extensive kingdom, which, before its conquest by the Dutch, comprehended a great extent of coast. The Straits of Macassar separate the island of Borneo from Celebes. They extend about 300 miles from north to south, and in average breadth 126 miles, excepting at the northern extremity, where it contracts to about sixty miles. It is of very dangerous navigation, abounding with shoals, rocks, and rocky islands, and in January and February a strong current is forced through this strait to the southward by the north winds.

MACAU, a town of France, in the department of the Gironde and arrondissement of Bordeaux, situated on the left bank of the Garonne, and containing 1800 inhabitants.

MACCABEES, two apocryphal books of Scripture, containing the history of Judas and his brothers, and their wars against the Syrian kings in defence of their religion and liberties, so called from Judas Mattathias, surnamed *Maccabæus*, as some say from the word מכבי, formed of the initials of מי כמכה כאלם יהוה, *Who is like unto thee, O Lord, amongst the gods*, which was the motto of his standard; and hence those who combated under his banner were called *Maccabees*, and the name was generally applied to all who had suffered in the cause of the true religion, under the Egyptian or Syrian kings. The first book of the Maccabees is an excellent history, and comes the nearest to the style and manner of the sacred historians. It was originally written in the Chaldaic tongue, and was extant in that language in the time of St Jerome. From the Chaldaic it was translated into Greek, from the Greek into the Latin. It is supposed to have been written by John Hyrcanus, the son of Simon, who was prince and high priest of the Jews for nearly thirty years, and began his government at the time where this history ends. It contains the history of forty years, from the reign of Antiochus Epiphanes to the death of Simon the high priest; that is, from the year of the world 3829 to the year 3869, or 131 years before Christ. The second book of the Maccabees begins with two epistles sent from the Jews of Jerusalem to the Jews of Egypt and Alexandria, to exhort them to observe the feast of the dedication of the new altar erected by Judas on his purification of the temple. The first was written in the 169th year of the era of the Seleucidæ, that is, 144 before Christ; and the second in the 188th year of the same era, or 125 before Christ. After these epistles follows the preface of the author to his history, which is an abridgment of a larger work, composed by one Jason, a Jew of Cyrene, who wrote in Greek the history of Judas Maccabæus and his brethren, and the wars against Antiochus Epiphanes, and Eupator his son. The second book does not by any means equal the accuracy and excellence of the first. It contains a history of about fifteen years, from the execution of the commission of Heliodorus, who was sent by Seleucus to fetch away the treasures of the temple, to the victory obtained by Judas Maccabæus over Nicanor; that is, from the year of the world 3828 to the year 3843, or 147 years before Christ.

There are in the Polyglot Bibles, both of Paris and London, Syriac versions of both these books; but they, as well as the English versions which we have amongst the apocryphal books in our Bible, are all derived from the Greek. There is also a third book of the Maccabees, containing the history of the persecution of Ptolemy Philopator against the Jews in Egypt, and their sufferings under it, which appears to have been written by some Alexandrian Jew in the Greek language, not long after the time of Siracides. It is in most of the ancient manuscript copies of the Greek Septuagint, particularly in the Alexandrian and the Vatican, but was never inserted into the vulgar Latin version of the

Bible, nor consequently into any of our English copies. Moreover, Josephus's history of the martyrs who suffered under Antiochus Epiphanes is found in some manuscript Greek Bibles, under the appellation of the fourth book of the *Maccabees*.

MACBETH, a Scotch nobleman in the eleventh century, nearly allied to Duncan, king of Scotland. Not contented with curbing the king's authority, he carried his ambition so far as to put him to death; and, chasing Malcolm Ceanmore his son and heir into England, usurped the crown. But Siward, earl of Northumberland, whose daughter Duncan had married, undertook, by the order of Edward the Confessor, the protection of the fugitive prince; marched with an army into Scotland; defeated and killed Macbeth; and restored Malcolm Greathead to the throne of his ancestors. Shakspeare has made this transaction the subject of one of his best tragedies.

MACCLESFIELD, a large market-town of the county of Chester, in the hundred of its own name, 168 miles north-west by north from London. It is pleasantly situated on an eminence at a short distance from the river Bollin. Many of the buildings in the principal streets are of a superior order. The town is lighted by gas, and well supplied with water derived from a spring on the neighbouring common. The river Bollin passes through the lower part of the town, and although the stream is small, it turns several mills. There are three established churches in the town, several dissenting places of worship, and a chapel for Roman Catholics. There is likewise a free grammar school, endowed with landed property of the yearly value of L.500, and a national school, with several Sunday schools. By the new municipal act, the town is divided into six wards; and the civil government is vested in a mayor, twelve aldermen, and thirty-six councillors. The justices of the peace are seven, one of them being the mayor for the time being. It returns two members to the House of Commons. There are markets on Monday and Saturday, which are well supplied. It was long celebrated for making buttons, silk-twist, sewing-silk, and bands for hats; but of late years these have been superseded by those of silk and cotton goods of various descriptions. The number and magnitude of the factories, as stated below, demonstrate the extent and importance of these manufactures, as connected with this town. There are also iron and brass founderies, nail factories, rope and twine works, and hat manufactories. The number of silk mills in the town, and in the remaining part of Prestbury parish, amounts to fifty-eight (eighteen of them being unemployed at the present time, 1836), and they furnish employment to 2429 males and 3525 females. The number of cotton mills is fourteen, employing 1370 males and 1429 females. The population amounted in 1801 to 8743, in 1811 to 12,999, in 1821 to 17,746, and in 1831 to 23,129.

Macedonia.

MACEDONIA, or MACEDON, a celebrated kingdom of antiquity, was bounded on the east by the Ægean Sea, on the south by Thessaly and Epirus, on the west by the Ionian Sea or Adriatic, on the north, at first by the river Strymon and the Scardian Mountains, but afterwards by the river Nessus or Nestus. In a direct line the whole country extended only 150 miles; but it was lengthened out to about three times that extent by the windings of the coast, in which almost every convenient situation was converted into a Grecian sea-port. The country was naturally divided, by the Thermaic and Strymonic Gulfs, into the provinces of Pieria, Chalcis, and Pangæus. The middle region, which took its name from a city of Eubœa, whence it had been originally peopled, was very fertile and pleasant; and the interior, being diversified by lakes, rivers, and arms of the sea, was extremely convenient for inland navigation, whilst the towns of Amphipolis, Potidæa, Acanthus, and many others, afforded marts for the commerce of the republics of Greece, as well as of Thrace and Macedonia. On one side of this district were the mountains of Pangæus, and on the other the plains of Pieria. The Pangæan Mountains, which extended ninety miles towards the east and the river Nessus, though proper neither for corn nor pasture, produced plenty of timber for ship-building; whilst the southern branches of the mountains contained rich veins of gold and silver; but these, though wrought successively by the Thasians and the Athenians, were only brought to perfection by Philip of Macedonia, who extracted from them gold and silver to the value of about L.200,000 sterling annually. Pieria extended fifty miles along the Thermaic Gulf, as far as the confines of Thessaly and Mount Pindus. The inland part of the country was beautifully diversified with shady hills and with fountains; and so admirably calculated for solitary walks and retirement, that the ancients looked upon it as the favourite haunts of the Muses, and accordingly bestowed upon them the title of *Pierides*.

Different names.

In the most ancient times this country was called *Æmathia*, from Æmathius, one of its princes. The name of *Macedonia* is said to have been derived from Macedo, a descendant of Deucalion; though others suppose it to have been only a corruption of *Mygdonia*, a district of the country. In those remote ages of antiquity, Macedonia, like most other countries of Europe, was divided into a great number of petty principalities, of which scarcely even the names are now known.

Kingdom founded by Caranus.

All authors agree, however, that Caranus was the first who established any permanent sovereignty in Macedonia. He was an Argive, a descendant of Hercules, and, about 800 years before Christ, conducted a small colony of his countrymen into the inland district of Macedonia, at that time distinguished by the name of Æmathia, as already mentioned. This territory was about 300 miles in circumference. On the south it was separated from the sea by a number of Greek republics, of which the most considerable were those of Olynthus and Amphipolis; and on the north, the east, and the west, it was surrounded by the barbarous kingdoms of Thrace, Pœonia, and Illyricum. According to the traditions of those times, Caranus having consulted the oracle respecting the success of his intended expedition, was commanded to follow the direction of the goats in the establishment of his empire. For some time he proceeded at random, without knowing what to make of the oracle's answer; but happening to enter the small kingdom of Æmathia, at that time governed by king Midas, he observed a herd of goats running towards Edessa, the capital. Recollecting the answer of the oracle, he then attacked and took the city by surprise, and soon afterwards made himself master of the whole kingdom. In memory of this remarkable event, he called the city *Ægæ*, and the people *Ægiates*, from the goats who conducted him, and made use of the figure of a goat for his standard. From this fable also we see why the figure of a goat is so frequently found on the coins of Philip and his successors.

But the little colony of Argives led into Æmathia by Caranus would soon have been overwhelmed by the barbarous nations who surrounded it, had not this prince and his subjects taken care to ingratiate themselves with their neighbours, rather than to attempt to subdue them by force of arms. They instructed them in the Greek religion and government, and in the knowledge of many useful arts; adopting themselves, in some degree, the language and manners of the barbarians, and imparting to them in return some portion of Grecian civilization. Thus they gradually associated with the fierce and warlike tribes in their neighbourhood; and this prudent conduct, being followed by succeeding generations, may be looked upon as one of the causes of the Macedonian greatness.

Perdiccas I.

Caranus dying after a short reign of three years, left the kingdom to his son Cœnus, who having considerably enlarged his dominions, was succeeded by Thurymas, and he again by Perdiccas I. This last prince is by Thucydides and Herodotus accounted the founder of the Macedonian monarchy, though his history is so obscured by fable that nothing certain can now be known concerning it. In process of time, however, the good understanding which had subsisted between the Macedonians and their barbarous neighbours began to suffer interruption, and in 691 B. C. the kingdom was for the first time invaded by the Illyrians. At first they did considerable damage by their ravages; but the Macedonian monarch Argæus having decoyed them into an ambush, cut off great numbers, and obliged the remainder to leave the kingdom. In the reign of his successors, however, they returned, and occasionally proved very troublesome enemies, till the reigns of Philip and Alexander.

Persians and Macedonians.

In the mean time, the kingdom of Macedonia began to be affected by those great events which had taken place in other parts of the world. Cyrus having overthrown the Babylonian empire, and conquered all the western part of Asia, established a mighty monarchy, which threatened the eastern parts of Europe with complete subjugation. The Greeks, however, having now emerged from barbarism, and acquired great knowledge in the art of war, were able effectually to resist this very formidable power; but the kingdom of Macedonia, obscure and unconnected, was obliged to yield, and though not formally made a province of the Persian empire, was nevertheless accounted in some sort as under the vassalage and protection of the Persians. Alcetas, who ascended the Macedonian throne about the time that the Persian monarchy was founded, had the dexterity to preserve his dominions from the encroachments of the Greeks on the one hand, and of the Persians on the other; but in the reign of his successor Amyntas, a formal demand was made of submission to the great king Darius, by sending him a present of earth and water. Seven ambassadors were sent upon this errand by Megabizus, one of the officers of Darius. They were sumptuously entertained by Amyntas; but having attempted to take some indecent liberties with the Macedonian women, Alexander, the king's son, caused them all to be put to death. This hasty retribution had almost proved the ruin of the kingdom; but Alexander found means to pacify Bubaris, the general sent against him by Megabizus, by showing him his sister Gygæa, a very beautiful woman, with whom the Persian fell in love at first sight, and afterwards married her.

From this time the Macedonians were accounted the faithful allies of the Persians; and Amyntas, through the interest of his son-in-law, obtained the country in the neighbourhood of Mount Hæmus and Olympus, at the same time that the city of Alabanda in Phrygia was given to Amyntas, the nephew of Alexander. The Macedonians distinguished themselves in the time of the Persian invasion of Greece, by furnishing their allies with 200,000 recruits; though some cities, particularly Potidæa, Olynthus, and Pallene, adhered to the Grecian interest. The last two were taken and razed, and the inhabitants massacred by the Persians; but Potidæa escaped by reason of the sea breaking into the Persian camp, where it did great damage. Alexander, however, afterwards thought proper to court the favour of the Greeks, by giving them intelligence of the time when Mardonius designed to attack them. The remaining transactions of this reign are entirely unknown, further than that the king enlarged his dominions as far as the river Nessus on the east, and the Axius on the west.

Reign of Perdiccas II.

Alexander I. was succeeded by his son Perdiccas II. who is said to have inherited his father's abilities, though not his integrity. From the duplicity with which he acted, both to the Greeks and the Persians, it does not appear indeed that he had much to boast of as to the latter quality. In the Peloponnesian war he espoused the cause of the Spartans against the Athenians, from whom he was in danger by reason of their numerous settlements on the Macedonian coast, and their great power by sea. For some time, however, he amused the Athenians with a show of friendship; but at last, under pretence of enabling Olynthus and some other cities to recover their liberties, he assisted in destroying the influence of the Athenians in those places, hoping to establish that of the Macedonians in its stead. But this design failed of success; the Olynthian confederacy was broken up; and the members of it became subject to Sparta, until at last, by the misfortunes of that republic, they grew sufficiently powerful, not only to resist the encroachments of the Macedonians, but to make considerable conquests in their country.

Archelaus I.

Perdiccas II. was succeeded about 416 B. C. by Archelaus I. He enlarged his dominions by the conquest of Pydna, and other places in Pieria, though his ambition seems rather to have been to improve his dominions than greatly to extend them. He facilitated the communication between the principal towns of Macedonia, by cutting straight roads through most part of the country; he built walls and fortresses in such places as afforded favourable situations; he encouraged agriculture and the arts, particularly those subservient to war; he formed magazines of arms; he raised and disciplined a considerable body of cavalry; and, in a word, he added more to the solid grandeur of Macedonia than had been done by all his predecessors put together. Nor was he regardless of the arts of peace. His palace was adorned by the works of the Grecian painters. Euripides was long entertained at his court; Socrates was earnestly solicited to live there, after the example of this philosophic poet, formed by his precepts, and cherished by his friendship; men of merit and genius in the various walks of literature and science were invited to reside in Macedonia, and treated with distinguished regard by a monarch equally attentive to advance his own glory and promote the happiness of his subjects.

Civil dissensions.

This great monarch died after a reign of six years, a space by far too short to accomplish the magnificent projects he had formed. After his death the kingdom fell under the power of usurpers, or of weak and wicked monarchs. A number of competitors constantly appeared for the throne; and these by turns called to their assistance the Thracians, Illyrians, Thessalians, the Olynthian confederacy, Athens, Sparta, and Thebes. Bardyllis, an active and daring chief, who, from being the head of a gang of robbers, had become sovereign of the Illyrians, entered Macedonia at the head of a numerous army; deposed Amyntas II. the father of Philip; and set up in his stead one Argæus, who consented to become tributary to the Illyrians. Another candidate for the throne, named Pausanias, was supported by the Thracians; but, by the assistance of the Thessalians and Olynthians, Amyntas was at length enabled to resume the government. After his restoration, however, the Olynthians refused to deliver up several places of importance belonging to Macedonia, which Amyntas had either intrusted to their care, or which they had taken from his antagonist. Amyntas complained to Sparta; and that republic, which had already formed schemes of very extensive ambition, so readily complied with the request, that it was generally supposed to have proceeded from Spartan emissaries sent into Macedonia. They pretended indeed to hesitate a little, and to take time to deliberate as to the army which ought to be raised for the purpose; but Cleigenes, the principal ambassador, so strongly represented the urgency of the case, that the troops which happened at that time to be ready were ordered to take the field without delay. Two thousand Spartans, under the command of Eudamidas, were ordered into Macedonia, whilst a powerful reinforcement under the command of Phœbidas, brother of the general, was ordered to follow him as soon as possible. By accident, Phœbidas and his auxiliaries were detained till the season for action had passed; but Eudamidas with his small army performed essential service. The appearance of a Spartan army at once encouraged the subjects and allies of the Olynthians to revolt; and the city of Potidæa, a place of great importance in the isthmus of Pallene, surrendered soon after his arrival in the country. Elated with his success, Eudamidas approached so near the city of Olynthus, that he was unexpectedly attacked, defeated, and killed, in a sally of the citizens. He was succeeded by Teleutias, brother of Agesilaus, who had under his command a body of ten thousand men, and was further assisted by Amyntas king of Macedonia, and Derdas his brother, the governor or sovereign of the most westerly province of Macedonia, which abounded in cavalry. By these formidable enemies the Olynthians were discomfited in a series of battles, obliged to shut themselves up in their city, and prevented from cultivating their territory; upon which Teleutias advanced with his whole forces to invest the city itself. But his excessive eagerness to destroy his enemies proved his ruin. A body of Olynthian horse had the boldness to pass the river Amnias in sight of the allied army, though so much superior in number. Teleutias ordered his targeteers to attack them, and the Olynthians retreated across the river, closely pursued by the Lacedæmonians, a great part of whom also crossed the river; but the Olynthians suddenly turned upon them, and killed upwards of one hundred, with Tlemonidas their leader. Teleutias, exasperated at this disaster, ordered the remainder of the targeteers and cavalry to pursue, whilst he himself advanced at the head of the heavy-armed foot with such celerity, that they began to fall into disorder. The Olynthians allowed them to come on, and the Lacedæmonians imprudently advanced under the towers and battlements of the city. The townsmen then mounted the walls, and discharged upon them a shower of darts, arrows, and other missile weapons, whilst the flower of the Olynthian troops, who had been purposely posted behind the gates, sallied forth and attacked them with the greatest fury. Teleutias, attempting to rally his men, was slain in the first onset; the Spartans who attended him were defeated, and the whole army dispersed with great slaughter, and obliged to shelter themselves in the towns of Acanthus, Apollonia, Spartolus, and Potidæa.

The Spartans, undismayed by this disaster, next sent their king Agesipolis with a powerful reinforcement into Macedonia. His presence greatly raised the spirits of the Lacedæmonian allies, and his rapid success seemed to promise a speedy termination to the war, when he himself died of a calenture. He was succeeded in the throne by his brother Cleombrotus, and in the command of the army by Polybiades, an old, experienced general, who likewise brought along with him a powerful reinforcement. Olynthus was now completely blocked up by land, whilst a squadron of Lacedæmonian galleys blockaded the neighbouring harbour of Myceberna. The Olynthians, however, held out for nine or ten months, but were at last obliged to submit on very humiliating conditions. They formally renounced all claim to the dominion of Chalcis, and ceded the Macedonian cities to their ancient governor; and in consequence of this Amyntas left the city of Ægæ or Edessa, where till now he had held his royal residence, and fixed it at Pella, a city of great strength and beauty, situated upon an eminence, which, together with a plain of considerable extent, was defended by impassable morasses, and also by the rivers Axius and Lydias. It was distant about fifteen miles from the Ægean Sea, with which it communicated by means of the above-mentioned rivers. It was originally founded by the Greeks, who had conquered and peopled it; but, in consequence of the misfortunes of Olynthus, it now became, and continued ever after to be, the capital of Macedonia.

Macedonia.

Pausanias; Ptolemy.

Amyntas being thus established in his dominions, continued to enjoy tranquillity during the remaining part of his life. The reign of his son Alexander was short, and disturbed by invasions of the Illyrians, from whom he was obliged to purchase a peace. He left behind him two brothers, Perdiccas and Philip, both very young, so that Pausanias again found means to usurp the throne, being supported not only by the Thracians, but by a considerable number of Greek mercenaries, as well as a powerful party in Macedonia itself. In this critical juncture, however, Iphicrates the Athenian happening to be on an expedition to Amphipolis, was so warmly addressed by Eurydice, the widow of Amyntas, in behalf of her two sons, whom she presented to him, that he interested himself in their behalf, and got Perdiccas, the eldest, established on the throne. He was induced to perform this act of generosity by the kindness which Eurydice and her husband had formerly shown to himself; and he likewise perceived the advantages which must ensue to his country from a connection with Macedonia. During the minority of the young prince, however, his brother Ptolemy, who was his guardian, openly aspired to the throne; but he was deposed by the Theban general Pelopidas, who reinstated Perdiccas in his dominions, and, in order to secure the dependence of Macedonia upon Thebes, carried along with him thirty Macedonian youths as hostages, amongst whom was Philip, the younger brother of the king. Perdiccas, elated by the protection of such powerful allies, now forgot Iphicrates and the Athenians, and even disputed with them the right to the city of Amphipolis, which had been decreed to them by the general council of Greece, but which his opposition rendered it impossible for them to recover. From the trust he put in these new allies, it is probable that he refused to Bardyllis the Illyrian the tribute the Macedonians had been obliged to pay him; a circumstance which occasioned a war with that nation. In this contest the Macedonians were defeated with the loss of four thousand men, and Perdiccas himself was taken prisoner, and soon afterwards died of his wounds.

State of the kingdom.

The kingdom was now left in the most deplorable state. Amyntas, the legitimate heir to the throne, was an infant; the Thebans, in whom Perdiccas had placed so much confidence, were deprived of the sovereignty of Greece; the Athenians, justly provoked at the ungrateful behaviour of the late monarch, showed a hostile disposition; the Illyrians ravaged the western, and the Pæonians the northern quarter of the kingdom; the Thracians still supported the cause of Pausanias, and proposed to send him into Macedonia at the head of a numerous army; whilst Argæus, the former rival of Amyntas, renewed his pretensions to the throne, and by flattering the Athenians with the hopes of recovering Amphipolis, easily induced them to support his claims, in consequence of which they fitted out a fleet, having on board three thousand heavy-armed soldiers, which they sent to the coast of Macedonia.

Arrival of Philip in Macedonia.

Philip, the late king's brother, no sooner heard of his defeat and death, than he set out privately from Thebes, and on his arrival in Macedonia found matters in the situation which we have just described. Fired with an insatiable ambition, it is probable that from the very first moment he had resolved to seize the kingdom for himself; yet it was necessary at first to pretend that he assumed the throne only to preserve it for his nephew. Philip, as has already been mentioned, had been carried off as a hostage by Pelopidas, but for a long time past had remained in such obscurity that historians are not agreed as to his place of residence, some placing him in Thebes, and others in Macedonia. It is certain, however, that from the age of fifteen he had been very much in the family of Epaminondas, from whose lessons he could not but derive the greatest advantage. It is also probable that he accompanied this celebrated general in many of his expeditions; and it is certain that, with an attendance suitable to his rank, he visited most of the principal republics, and paid great attention to their institutions, both civil and military. Having easy access to whomsoever he pleased, he cultivated the friendship of the first people in Greece. Even in Athens, where no good will subsisted to Macedonia, the philosophers Plato, Isocrates, and Aristotle, cultivated his acquaintance; and the connection he formed with the principal leaders of that republic in the early period of his life no doubt contributed greatly to the accomplishment of the designs in which he afterwards proved so successful.

Affairs of the kingdom retrieved by him.

His appearance in Macedonia instantly changed the face of affairs. The Macedonian army, though defeated, was not entirely destroyed; and the remainder of them secured themselves in the fortresses which had been built by Archelaus. There were also considerable garrisons in the fortresses, and walled towns scattered over the kingdom; and the Illyrians, who had made war only for the sake of plunder, soon returned home to enjoy the fruits of their victory. His other enemies, the Thracians and Pæonians, were much less formidable than the Illyrians, being still in a very rude and uncivilized state, incapable of uniting under one head in such a manner as to bring any formidable army into the field. Whilst the Illyrians therefore gave up the campaign through mere caprice and unsteadiness, Philip himself applied to the Pæonians, and by fair promises and flattery prevailed upon them to desist. The king of Thrace, by means of a sum of money, was easily prevailed upon to abandon the cause of Pausanias; so that Philip, freed from these barbarians, was now at liberty to oppose the Athenians, who supported Argæus, and threatened a very formidable invasion.

Philip assumes the sovereignty.

The appearance of the Athenian fleet before Methone, with that of Argæus at the head of a numerous army in Pieria, filled the whole country with consternation; and Philip, who was by no means deficient in the talents necessary to recommend himself to the good graces of the people, took the opportunity of getting Amyntas set aside, and himself declared king, for which proceeding indeed the danger of the times afforded a very plausible pretext. In the mean time, Argæus advanced with his Athenian allies towards Edessa or Ægæ, the ancient capital of the Macedonian empire, where he hoped to have been amicably received; but finding the gates shut against him, he returned back to Methone. Philip harassed him in his retreat, cutting off great numbers of his men, and afterwards defeated him in a general engagement, in which Argæus himself, with the flower of his army, was cut in pieces, and the rest taken prisoners. This first instance of success contributed greatly to raise the spirits of Philip's party; and he himself took care to improve it in the best manner possible. Having made a great number of prisoners, both Macedonians and Athenians, he determined, by his treatment of them, to ingratiate himself with both parties. The former were called into his presence, and, after a gentle reprimand, admitted to swear allegiance to him, after which they were distributed throughout the army. The Athenians were entertained at his table, and dismissed without ransom, and their baggage was restored to them. The prisoners were just allowed time to return to their native city, and to spread abroad the news of Philip's generosity, when they were followed by ambassadors from Macedonia with proposals for peace. As he knew that the loss of Amphipolis had greatly irritated them, he now thought proper to renounce his jurisdiction over that city. It was accordingly declared free and independent, and subject only to the government of its own free and equitable laws. This prudent conduct, together with his kind treatment of the prisoners, so wrought upon the minds of the Athenians, that they consented to the renewal of a treaty which had formerly subsisted between them and his father Amyntas. Thus he found means to remove all jealousy of his ambition, and to induce them to engage in a ruinous war with their allies, which occupied their attention until Philip had an opportunity of getting matters so well established that it was impossible to overthrow him.

The power of the nobility reduced.

The new king being thus at liberty to regulate his domestic concerns, began to circumscribe the power of his chiefs and nobles, who, especially in the more remote provinces, paid very little regard to the authority of the kings of Macedonia; sometimes, even in times of public calamity, throwing off their allegiance altogether, and assuming an independent jurisdiction over considerable tracts of country. To counteract the ambition of these chiefs, Philip chose a body of the bravest Macedonian youths, whom he entertained at his own table, and honoured with many testimonies of his friendship, giving them the title of his "companions," and allowing them constantly to attend him in war and hunting. Their intimacy with the sovereign, which was considered as a sure indication of their merit, obliged them to use superior diligence in all the severe duties of military discipline; and the young nobility, eager to participate in such high honours, vied with one another in their endeavours to gain admission into this distinguished order; so that whilst on the one hand they served as hostages, they formed on the other an useful seminary for future generals, by whom both Philip and Alexander were afterwards greatly assisted in their conquests.

The phalanx.

Diodorus Siculus, and all the Roman writers who have treated of the history of Greece, assert that Philip, in the first year of his reign, instituted the Macedonian phalanx; a body of six thousand men armed with short swords fitted either for cutting or thrusting, having also strong bucklers four feet long and two and a half broad, and pikes fourteen feet long, and usually marching sixteen men deep. But this opinion is controverted by others. Dr Gillies supposes that such an opinion had arisen from the Romans meeting with the phalanx in its most complete form in Macedonia; and as they became acquainted with Greece and Macedonia pretty nearly at the same time, it was natural for them to suppose that it had been invented amongst the Macedonians. The phalanx, he says, is nothing different from the armour and arrangement which had always prevailed amongst the Geeeks, and which Philip adopted in their most perfect form; "nor is there reason to think that a prince, who knew the danger of changing what the experience of ages had approved, made any alteration in the weapons or tactics of that people.[1] The improvement in the countermarch, to which Philip gave the appearance of advancing instead of retreating, mentioned by Ælian in his Tactics (cap. xxviii.), was borrowed, as this author tells us, from the Lacedæmonians. If Philip increased the phalanx, usually less numerous, to six thousand men, this was far from an improvement; and the latter kings of Macedonia, who swelled it to sixteen thousand, only rendered that order of battle more unwieldy and inconvenient." Instead of this, Philip, according to our author, employed himself in procuring arms, horses, and other necessary materials for war; and in introducing a more severe and exact military discipline than had formerly been known in Macedonia.

---

[1] Dr Gillies is mistaken as to the constitution of the Macedonian phalanx, which was a deeper, more compact, and perfect formation than that which, under the same name, obtained amongst the Greeks. See the article **ARMY**.

Whilst the king thus took the best methods to render himself secure at home and formidable abroad, the Pæonians again began to make incursions into the kingdom. The death of Agis, their king, however, who was a man of great military skill, deprived them of almost all power of resistance when they were attacked. Philip, in consequence, overran their country with little opposition, and reduced them to the state of tributaries to Macedonia. No sooner was this accomplished, than he undertook a winter's campaign against the Illyrians, who had long been the natural enemies of Macedonia. They had now extended their territory to the east, by which means the Macedonians were excluded from the harbours upon the coast of the Adriatic. This was a grievance to Philip, who seems early to have meditated the formation of a naval force; neither could he hope to be in safety, should the kingdom be left open to the incursions of a barbarous enemy; for which reason he determined at once to humble those enemies in such a manner that they should no longer be in a situation to give him any disturbance. After an ineffectual negociation, he was met by Bardyllis at the head of a considerable body of infantry, but with only four hundred horse. They made a gallant resistance for some time; but being unable to contend with so skilful a general as Philip, they were defeated with the loss of seven thousand men, amongst whom was their leader Bardyllis, who fell at the age of ninety.

By this disaster the Illyrians were so much disheartened, that they sent ambassadors to Philip, humbly begging for peace upon any terms. The conqueror granted them the same conditions which had been imposed upon the Pæonians, viz. becoming tributary, and yielding up to him a considerable part of their country. That part of it which lay to the eastward of a lake named Lychnidus he annexed to Macedonia, and probably built a town and settled a colony there, the country being fertile, and the lake abounding with many kinds of fish highly esteemed by the ancients. This town and lake were about fifty miles distant from the Ionian Sea; and such was the ascendency which the arms and policy of Philip acquired over his neighbours, that the inhabitants of all the intermediate district soon adopted the language and manners of their conquerors; whilst their territory, hitherto unconnected with any foreign power, sunk into such absolute dependence upon Macedonia, that many ancient geographers supposed it to be a province of that country.

Philip had no sooner reduced the Illyrians, than he began to put in execution greater designs than any which he had yet attempted. The rich coasts to the southward of Macedonia, inhabited chiefly by Greeks, presented a strong temptation to his ambition and avarice. The confederacy of Olynthus, after having thrown off the yoke of Sparta, had become more powerful than ever, and could send into the field an army of ten thousand heavy-armed troops, besides a number of cavalry in proportion; most of the towns in Chalcidice had become its allies or subjects; whilst this populous and wealthy province, together with Pangæus on the right and Pieria on the left, of both which the cities were either independent or subject to the Athenians, formed a barrier sufficient to guard against any incursions of the Macedonians. But though Philip was sensible enough of the importance of those places, he considered the conquest of Amphipolis as more necessary at that time. By the possession of this place, Macedonia would be connected with the sea, and would be secured in many commercial advantages, which could not but contribute greatly to the prosperity of the kingdom at large; a road was likewise opened to the woods and mines of Pangæus, the former of which were so necessary to the formation of a naval force, and the latter for the establishment of a proper military force. This city had indeed been declared independent by Philip himself in the beginning of his reign; but this was only to prevent a rupture with the Athenians, who still asserted their right to it as an ancient colony, though, by reason of the perfidy of Charidemus, a native of Eubœa, they had hitherto failed in their attempts to recover it. The Amphipolitans, however, having once enjoyed the sweets of liberty, prepared to maintain themselves in their independence. In the mean time, the hostile designs of Philip, which all his precaution had not been able to conceal, alarmed the inhabitants to such a degree that they thought proper to put themselves under the protection of the Olynthians. By them they were readily received into the confederacy, and, trusting to the strength of their new allies, behaved in such an insolent manner to Philip, that he was not long in finding a specious pretext for hostility; on which the Olynthians, greatly alarmed, sent ambassadors to Athens, requesting their assistance against such a powerful enemy. Philip, however, justly alarmed at such a formidable conspiracy, sent agents to Athens with such expedition that they arrived there before any thing could be concluded with the Olynthian deputies. Having gained over the popular leaders and orators, he deceived and flattered the magistrates and senate in such an artful manner, that a negociation was instantly set on foot, by which Philip engaged to conquer Amphipolis for the Athenians, upon condition that they surrendered to him the strong fortress of Pydna, a place which he represented as of much less importance to them; promising also to confer upon them many other advantages, which, however, he did not specify at that time. Thus the Athenians, deceived by the perfidy of their own magistrates, elated with the hopes of recovering Amphipolis, and outwitted by the superior policy of Philip, rejected with disdain the proffers of the Olynthians.

The ambassadors of Olynthus returned home highly disgusted with the reception they had met with, but had scarcely time to communicate their news to their countrymen, when the ambassadors of Philip arrived at Olynthus. He pretended to condole with them on the affront they had received at Athens, but also testified his surprise that they should court the assistance of that distant and haughty republic, when they could avail themselves of the powerful kingdom of Macedonia, which wished for nothing more than to enter into equal and lasting engagements with their confederacy. As a proof of his moderation and sincerity, he offered to put them in possession of Anthemus, an important town in the neighbourhood, of which the Macedonians had long claimed the jurisdiction; making many other fair promises, and, amongst the rest, that he would reduce for them the cities of Pydna and Potidæa, which he chose rather to see in dependence on Olynthus than Athens. Thus he prevailed upon the Olynthians not only to abandon Amphipolis, but to assist him with all their power in the execution of his designs.

Philip now lost no time in executing his purposes against Amphipolis, and pressed the city so closely that the people were glad to apply to the Athenians for relief. Accordingly, they despatched two of their most eminent citizens, Hierax and Stratocles, to represent the danger of an alliance between Philip and the Olynthians, and to profess their sorrow for having so deeply offended the parent state. This representation had such an effect, that though the Athenians were then deeply engaged in the Social War, they would probably have paid some attention to the Amphipolitans, had not Philip taken care to send them a letter with fresh assurances of friendship, acknowledging their right to Amphipolis, and which he hoped shortly to put into their hands in terms of his recent agreement. By these specious pretences the Athenians were persuaded to pay as little regard to the deputies of the Amphipolitans as they had already done to those of the Olynthians; so that the city, unable to defend itself alone against so powerful an enemy, at last surrendered at discretion in the year 357 before Christ.

Philip still proceeded in the same cautious and politic manner in which he had commenced. Though the obstinate defence of the Amphipolitans might have furnished a pretence for severity, he contented himself with banishing a few of the popular leaders, from whom he had most cause to dread opposition, treating the rest of the inhabitants with all manner of clemency; but he took care to add Amphipolis to his own dominions, from which he was determined that it never should be separated, notwithstanding the promises he had made to the Athenians. Finding that it was not his interest at this time to fall out with the Olynthians, he cultivated the friendship of that republic with great assiduity; and took the cities of Pydna and Potidæa, which he readily yielded to the Olynthians, though they had given him but little assistance in the reduction of these places. Potidæa had been garrisoned by the Athenians, and them the artful king sent back without ransom, lamenting the necessity of his affairs, which obliged him, contrary to his inclination, to oppose their republic. Though this was rather too gross, the Athenians were then so much engaged with the Social War, that they had not leisure to attend to the affairs of other nations. Philip made the best use of his time, and next projected the conquest of the gold mines of Thrace. That rich and fertile country was now held by one Cotys, a prince of such weak intellectual faculties, that the superstition of the Greeks, into which he was newly initiated, had almost entirely subverted his reason, and he wandered about in quest of the goddess Minerva, with whom he fancied himself in love. The invasion of the Macedonians, however, awaked him from his reverie; and Cotys, finding himself destitute of other means of opposition, attempted to stop the progress of the enemy by a letter. To this Philip paid no regard, and the Thracians were instantly expelled from their possessions at Crenidæ, where there were very valuable gold mines. These had formerly been worked by colonies from Thasos and Athens; but the colonists had long since been expelled by the barbarous Thracians, who knew not how to make use of the treasure they were in possession of. Philip took the trouble to descend into the mines himself, in order to inspect the works; and, having caused them to be repaired, planted a Macedonian colony at Crenidæ, bestowed upon it the name of Philippi, and drew annually from the gold mines to the value of near 1000 talents, or L.200,000 sterling, an immense sum in those days. The coins struck here were likewise called Philippi.

The affairs of Thessaly settled.

Philip having obtained this valuable acquisition, next undertook to settle the affairs of Thessaly, where everything was in the greatest confusion. This country had been formerly oppressed by Alexander, tyrant of Pheræ, after whose death three others appeared, viz. Tissiphornus, Pitholaus, and Lycophron, the brothers-in-law of Alexander, who had likewise murdered him. By the united efforts of the Thessalians and Macedonians, however, these usurpers were easily overthrown, and effectually prevented from making any disturbances for the future; and the Thessalians, from a mistaken gratitude, surrendered to Philip all the revenues arising from their fairs and towns of commerce, as well as all the conveniences of their harbours and shipping; a concession which Philip took care to secure in the most effectual manner.

Having now not only established his sovereignty in the most effectual manner, but rendered himself very powerful and formidable to his neighbours, Philip determined to enjoy some repose from his fatigues. Having formed an alliance with Arybbas, king of Epirus, he, in the year 357 before Christ, married Olympias, the sister of that prince; a match thought the more eligible, as the kings of Epirus were supposed to be descended from Achilles. The nuptials were solemnized with great pomp at Pella, and several months were spent in shows and diversions, during which Philip showed such an extreme proneness to vice of every kind, as disgraced him in the eyes of his neighbours, and most probably laid the foundation of his future domestic unhappiness. So much was this behaviour of the Macedonian monarch taken notice of by the neighbouring states, that the Pæonians and Illyrians threw off the yoke, engaging in their schemes the king of Thrace; and, notwithstanding the insane state of that prince, their designs were now carried on with more judgment than was usual with barbarians. Philip, however, notwithstanding his dissipation, got warning of his danger in sufficient time to prevent the evil consequences which might have ensued had the confederates had time to bring their schemes to a proper bearing. Early in the spring of 356 he took the field with the flower of the Macedonian troops. Having marched in person against the Pæonians and Thracians, he despatched Parmenio, his best general, into Illyria. Both enterprises proved successful; and whilst Philip returned victorious from Thrace, he received an account of the victory gained by Parmenio; a second messenger informed him of a victory gained by his chariot at the Olympic games; and a third announced that Olympias had been delivered of a son at Pella.

A general combination against Philip.

Alexander the Great.

This was the celebrated Alexander, to whom the diviners prophesied the highest prosperity and glory, as being born in such auspicious circumstances. A short time after the birth of Alexander, Philip wrote a letter to the philosopher Aristotle, whom he chose as preceptor to his son. The letter was written with great brevity, containing only the following words: "Know that a son is born to us. We thank the gods not so much for their gift, as for bestowing it at a time when Aristotle lives. We assure ourselves that you will form him a prince worthy of his father, and worthy of Macedonia."

He next set about the further enlargement of his territories, which were already very considerable. Pæonia now formed one of his provinces; on the east his dominions extended to the sea of Thasos, and on the west to the lake Lychnidus. The Thessalians were in effect subject to his jurisdiction, and the possession of Amphipolis had secured him many commercial advantages. He had a numerous and well-disciplined army, with plentiful resources for supporting such an armament, and carrying through the other schemes suggested by his ambition, though his deep and impenetrable policy rendered him more truly formidable than all these put together. His first scheme was the reduction of Olynthus, the most populous and fertile country upon the borders of Macedonia, after which his ambition prompted him to aspire to the sovereignty of all Greece. To accomplish the former, he had hitherto courted the friendship of the Olynthians by every possible method; and without letting slip any opportunity to accomplish the latter, he gradually deprived the Athenians of several of their settlements in Thrace and Macedonia. In these depredations, however, he took care always to give such appearance of justice to his actions, that his antagonists, who had studied the matter less deeply, could not find a plausible pretext for engaging in war against him, even when he had openly committed hostilities against them. Philip easily perceived that the affairs of the Greeks were coming to a crisis, and he determined to watch the issue of their mutual dissensions. Nor did that result disappoint his expectations. The Phocians had violated the religion of those days in a most extraordinary manner; they had even ploughed up the lands consecrated to Apollo; and, however they might pretend to excuse themselves by examples, the Amphictyons fulminated a decree against them, commanding the sacred lands to be laid waste, and imposing a heavy fine upon the community.

By this decree all Greece was again involved in the war called *Phocian*, from the name of the city about which it commenced. Philip at the beginning of the troubles was engaged in Thrace, where a civil war had broken out amongst the sons of Cotys; and wherever Philip interfered, it was certain that matters turned out to his own advantage. His encroachments at length became so enormous, that Kersobletes, the most powerful of the contending princes, agreed to cede the Thracian Chersonesus to the Athenians, who immediately sent Chares at the head of a powerful armament to take possession of it. In this expedition the town of Sestos was taken by storm, and the inhabitants were cruelly treated by Chares, whilst Philip employed himself in the siege of Methone in Pieria. This city he likewise reduced; but the king lost an eye at the siege, and in a very extraordinary manner, if we may give credit to the accounts of some ancient historians. A celebrated archer, named Aster, had, it seems, offered his services to Philip, being represented as such an excellent marksman that he could hit the swiftest bird on the wing. Philip replied that he would be of excellent use if they were to make war with starlings. Aster, disgusted with this reception, went over to the enemy, and with an arrow wounded the king in the eye. When the weapon was extracted, it was found to be inscribed with these words: "For the right eye of Philip." The king ordered the arrow to be shot back again, with another inscription, importing that he would cause Aster to be hanged when the town was taken. A report was raised after Philip's death that he had lost his eye by prying too narrowly into the amours of Olympias and Jupiter Ammon, which the vanity of his successor prompted him to cherish, as his flatterers had probably been the inventors of it.

During all this time the Phocian war raged with the greatest fury, and involved in it all the states of Greece. Lycophron, one of the Thessalian tyrants whom Philip had formerly deprived of his authority, had again found means to re-establish himself; and his countrymen having taken part with the Phocians, Lycophron called in Onomarchus, the Phocian general, to protect him against the power of Philip, by whom he was sensible that he would soon be attacked. The king accordingly marched into Thessaly with a considerable army, and defeated Phyallus, the brother of Onomarchus, whom the latter had sent into the country with a detachment of seven thousand men. After this he besieged and took the city of Pegasæ, driving the enemy towards the frontiers of Phocis. Onomarchus then advanced with the whole army; and Philip, though inferior in numbers, did not decline the engagement. The Phocians at first gave ground, on which the Macedonians pursued, in good order; but coming near a precipice, on the top of which Onomarchus had posted a detachment of soldiers, the latter rolled down stones and fragments of the rock in such a manner as did dreadful execution, and threw them into the utmost disorder. Philip, however, rallied his troops with great presence of mind, and prevented the Phocians from gaining any further advantage; saying, as he withdrew his troops, that they did not retreat through fear, but only like rams, in order to strike with the greater vigour. Nor was he long before he made good his assertion; for, having recruited his army with the greatest expedition, he returned into Thessaly at the head of twenty thousand foot and five hundred horse, and was there met by Onomarchus. The Macedonians at this time were superior in number to their enemies; and Philip, moreover, took care to remind them that their quarrel was that of heaven, and that their enemies had been guilty of sacrilege, by profaning the temple of Delphi. That they might be still more animated in the cause, he put crowns of laurel on their heads. Thus fired with enthusiasm, and having besides the advantage of numbers, the Phocians were altogether unable to withstand them. They threw away their arms and fled towards the sea, where they expected to have been relieved by Chares, who, with the Athenian fleet, was near to the shore; but in this they were disappointed, for he made no attempt to save them. Upwards of six thousand perished in the field of battle or in the pursuit, and three thousand were taken prisoners. The body of Onomarchus being found amongst the slain, was by order of Philip hung upon a gibbet as a mark of infamy, on account of his having polluted the temple; and the bodies of the rest were thrown into the sea, as being all partakers of the same crime. The fate of the prisoners is not known, by reason of an ambiguity in a sentence of Diodorus Siculus, which may imply that they were drowned, though he does not expressly say so.

Philip pursues his ambitious schemes.

After this victory Philip set about the settlement of Thessaly, waiting only for an opportunity to put in execution his favourite scheme of invading Greece. In the mean time, he rejoiced to see the different states weakening each other by their mutual dissensions, of which he never failed to take advantage as far as possible. He now, however, began to throw off the mask with regard to the Olynthians, whom he had long deceived with fair promises. Having detached Kersobletes from the interest of the Athenians, he established him in the sovereignty of Thrace; not out of any good will, but with a view to destroy him whenever a proper opportunity should present itself. Were he once possessed of the dominions of that prince, the way to Byzantium was open to him, the possession of which must have been a great temptation to a prince who well knew how to value the importance of its situation both with respect to commerce and war; and in order to pave the way to this important conquest, he attacked the fortress of Heræum, a small, and in itself unimportant place, though, by reason of its neighbourhood to Byzantium, a highly valuable acquisition. The Athenians, however, at last began to perceive the designs of Philip, and determined to counteract them. For this purpose they entered into an alliance with Olynthus; and having warned Kersobletes of his danger, they ordered a powerful fleet to the defence of Heræum. But these vigorous measures were soon counteracted by the report of Philip's death, which had been occasioned by his wound at Methone, and a distemper arising from the fatigues which he had afterwards undergone. The inconstant Athenians too easily gave credit to this report, and, as if all danger had been over with his death, discontinued their preparations, and directed their whole attention to the Sacred War. This contest, instead of being ended by the death of Onomarchus, now raged with redoubled fury. Phyallus, above mentioned, the only surviving brother of Onomarchus, undertook the cause of the Phocians; and his affairs becoming every day more and more desperate, he took the most unaccountable method of retrieving them which could be imagined, having converted into ready money the most precious materials belonging to the temple at Delphi, and with this treasure doubled the pay of his soldiers. By this new piece of sacrilege he indeed brought many adventurers to his standard, though he cut off all hopes of mercy for himself or his party should he be defeated. Having the assistance of a thousand Lacedæmonians, two thousand Achæans, and five thousand Athenian infantry, with four hundred cavalry, he was still enabled to make a very formidable appearance; and the Phocians took the field with every prospect of success.

Designs of Philip against Greece.

Philip now thought it time to throw off the mask entirely, for which the proceedings of the Athenians, particularly their league with Olynthus, furnished him with a plausible pretext; and the revenging such horrid sacrilege as had been committed at Delphi seemed to give him a title to march at the head of an army into Greece. The superstition of the Greeks, however, had not yet blinded them to such a degree but they could easily perceive that Philip's piety was a mere pretence, and that his real design was to invade and conquer the whole country. The Athenians no sooner heard of the march of the Macedonian army, than they despatched with all expedition a strong guard to secure the pass of Thermopylæ; so that Philip was obliged to return greatly chagrined and disappointed. Their next step was to call an assembly to deliberate upon the measures proper to be taken in order to restrain the ambition of the Macedonian monarch; and this assembly is rendered memorable by the first appearance of Demosthenes as an orator against Philip. Athens had for some time been in a very alarming situation. They were deeply involved in the Sacred War; their northern possessions were continually insulted and plundered by Philip; whilst a number of his mercenary partisans drew off the public attention to such a degree, that, instead of taking measures to counteract that ambitious prince, they amused themselves with speculations about the designs of the Persian monarch, who was preparing for war against the Cyprians, Egyptians, and Phœnicians. Isocrates the celebrated orator, and Phocion the statesman, joined the multitude in their opinion, though not from any servile or mercenary motives, but purely from a sense of the unsteady conduct of the Athenians, who, they were assured, could not contend with a prince of the vigour and activity of Philip, and therefore exhorted them by all means to cultivate the friendship of a king whom they could not oppose with any probability of success. Isocrates, indeed, greatly wished for an expedition into Asia, and looked upon Philip as the only general capable of conducting it, though at present the Greeks had no pretence for making war upon the Persians, except that of revenging former injuries. On this subject he addressed a discourse to Philip himself; and it is even said that Isocrates, by the power of his rhetoric, prevailed upon Philip and the Athenians to lay aside for a short time their animosities, and consent to undertake this expedition in conjunction.

Demosthenes.

If this coalition, however, did really take place, it was of but very short duration. The views of Phocion and Isocrates were violently opposed by Demosthenes. Though sensible of the corruption and degeneracy of his countrymen, he hoped to be able to rouse them from their lethargy by dint of his eloquence; a talent he had been at great pains to cultivate, and in which he is said to have excelled all men that ever existed. In his first addresses to the people, this celebrated orator exhorted them to awake from their indolence, and to assume the direction of their own affairs. They had been too long governed, he said, by the incapacity of a few ambitious men, to the great disadvantage as well as disgrace of the community. In the first place, an orator who had placed himself at the head of a faction of no more than three or at the most four hundred, availed himself and his followers of the carelessness and negligence of the people, to rule them at pleasure. From a consideration of their present weakness and corruption, as well as of the designs and commotions of the neighbouring powers, he advised them to abandon all romantic and distant schemes of ambition; and, instead of carrying their arms into remote countries, to prepare for repelling the attacks which might be made upon their own dominions. He insisted also upon a better regulation of their finances; a more equal distribution of the public burdens, in proportion to the abilities of those upon whom they were laid, and the retrenchment of many superfluous expenses. Having pointed out in a strong light the vigorous conduct of Philip, and shown by what means he had attained to such a respectable footing in the world, he next laid down a proper plan for their military operations. He told them that they were not yet prepared to meet Philip in the field. They must begin with protecting Olynthus and the Chersonesus, for which it would be necessary to raise a body of two thousand light-armed troops, with a due proportion of cavalry, which ought to be transported under a proper convoy to the islands of Lemnos, Thasos, and Sciathos, in the neighbourhood of Macedonia. In these they would enjoy all kinds of necessaries in abundance, and might avail themselves of every favourable incident to appear at the first summons of their allies, and either to repel the incursions of the Macedonians, or harass their territories. Whilst this was going on, more vigorous preparations might be made for war at home; and it was proposed that only the fourth part of the Athenian citizens should enlist, and no more supplies were wanted at present but ninety talents. But notwithstanding the moderation of these proposals, and the urgent necessities of the state, it was impossible to prevail upon the indolent and careless Athenians to provide for their own safety. They appear, indeed, at this time, to have been desperately sunk in effeminacy and dissipation; a disposition which Philip took care to encourage to the utmost of his power. There was an assembly in the city called the Sixty, from their consisting originally of that number, who met expressly for the purposes of extinguishing all care about public affairs, and of intoxicating themselves with every kind of pleasure which they had in their power. With this assembly Philip was so well pleased, that he sent them money to support their extravagances; and so effectually did they answer his purposes, that all the eloquence of Demosthenes could not counteract the speeches of much inferior orators when their eloquence was backed by Macedonian gold.

Philip himself, as we have already hinted, was excessively debauched in his private character, and the most shameful stories are related of him by the ancient writers, particularly by Demosthenes. Theopompus, too, an author who flourished in the time of Alexander, and was rewarded and honoured by that monarch, also speaks of him in terms which cannot be mentioned with decency; but these accounts, coming from the avowed enemies of the king, are scarcely to be credited; and perhaps policy, as well as inclination, might contribute somewhat to this scandalous behaviour, that he might thereby recommend himself to the libertines of Athens, and prevent even many of the more thinking part of the people from suspecting his designs. But in whatever excesses he might at times indulge, he never once lost sight of his main object, the subjugation of the Greek states. On pretence of being in want of money to defray the expense of his buildings, he borrowed money at a very high price throughout the whole country; and this he found an easy matter to do, as the dissipation of the Delphic treasures had rendered cash very plentiful in Greece. Thus he attached his creditors firmly to his own interest; and, on pretence of paying debts, was enabled, without molestation, to bestow a number of pensions and gratuities upon the Athenian orators, who by their treacherous harangues contributed greatly to the ruin of their country; at least as far as it could be ruined by subjection to a prince who would have obliged them to remain at peace, and apply themselves to the useful arts. These he himself encouraged in a very eminent degree. The greater part of his time was employed at Pella, which city he adorned in the most magnificent manner, with temples, theatres, and porticos. He invited by liberal rewards the most ingenious artists to be found in Greece; and as many of these met with very little encouragement in their own country, great numbers flocked to him from all quarters. In the government of his people, also, Philip behaved with the utmost impartiality; listening with condescension to the complaints of the meanest of his subjects, and keeping up a constant correspondence with those whom he thought worthy of his acquaintance; from which it is not easy to imagine how he could be guilty of the vices which have been imputed to him by some of the ancient historians.

The fate of Olynthus was now soon determined. This city, which held the balance of power between Athens and Macedonia, was taken and plundered, and the inhabitants sold as slaves; but the chief hope of Philip was in putting an end to the Phocian war. For this purpose he affected a neutrality, that he might thereby become the arbiter of Greece. His hopes were well founded; for the Thebans, who were at the head of the league against the Phocians, solicited him on the one side, and the states confederated with the Phocians did the same on the other. He answered neither, yet held both in dependence. In his heart he favoured the Thebans, or rather placed his hopes of advancing his own cause on that state; for he well knew that the Athenians, Spartans, and other states allied with Phocis, would never allow him to pass Thermopylæ, and lead an army into their territories. So much respect, however, did he show to the ambassadors from these states, particularly Ctesiphon and Phrynon, who came from Athens, that they believed him to be in their interest, and reported as much to their masters. The Athenians, who were now dissolved in ease and luxury, received this news with great satisfaction, and immediately named ten plenipotentiaries to go and treat of a full and lasting peace with Philip. Amongst these plenipotentiaries were Demosthenes and Æschines, the most celebrated orators in Athens. Philip gave directions that these ambassadors should be treated with the utmost civility, naming, at the same time, three of his ministers to confer with them, namely, Antipater, Parmenio, and Eurylochus. Demosthenes being obliged to return to Athens, recommended it to his colleagues not to carry on their negociations with Philip's deputies, but to proceed with all diligence to court, there to confer with the king himself. The ambassadors, however, were so far from following his instructions, that they suffered themselves to be put off for three months by the arts of Philip and his ministers.

In the mean time, the king took from the Athenians such places in Thrace as might best cover his frontiers, giving their plenipotentiaries, instead of them, abundance of fair promises, and the strongest assurances that his good will should be as beneficial to them as ever their colonies had been. At last a peace was concluded; but then the ratification of it was deferred until Philip had obtained possession of Pherea in Thessaly, and saw himself at the head of a numerous army; then he ratified the treaty, and dismissed the plenipotentiaries with assurances that he would be ready at all times to give the Athenians proofs of his friendship. On their return to Athens, when this matter came to be debated before the people, Demosthenes plainly told them that, in his opinion, the promises of Philip ought not to be relied on, because they appeared to be of little significance in themselves, and came from a prince of so much art, and so little fidelity, that they could derive no authority from their maker. Æschines, on the other hand, gave it as his opinion, that the king of Macedonia's assurances ought to give full satisfaction. He said, that, for his own part, he was not politician enough to see any thing of disguise or dissimulation in the king's conduct; that there was great danger in distrusting princes; and that the surest method of putting men upon deceit was to show that we suspected them of it. In this the rest of the plenipotentiaries concurred with Æschines; and the people, being desirous of quiet, and addicted to pleasure, easily gave credit to all that was said, and decreed that the peace should be maintained. All this was the more easily brought about, because Phocion, the worthiest man in the republic, did not oppose Philip, which was owing to his entertaining a just sense of the actual state of his country. He conceived that the Athenians of those times were nothing like their ancestors; and therefore, as he expressed himself upon another occasion, he was desirous, since they would not be at the head of Greece themselves, that they should at least be upon good terms with that power which would unquestionably be so.

End of the Phocian war.

Philip, who knew how to use as well as to procure opportunity, whilst the Athenians were in this good humour, passed Thermopylæ, without their knowing whether he would fall upon Phocis or Thebes; but he quickly undeceived them, by commanding his soldiers to put on crowns of laurel, declaring them thereby the troops of Apollo, and himself the lieutenant-general of that god. He then entered Phocis with an air of triumph, which so terrified the Phocians, whom he had caused to be denounced as sacrilegious persons, that they immediately dismissed all thoughts of defence, and without more ado submitted to his mercy. Thus the Phocian war, which had so long employed all Greece, was ended without a stroke, and the judgment on the Phocians remitted to the Amphictyonic or grand council of Greece. By their decree, the walls of three Phocian cities were demolished, the people were forbidden to inhabit any but villages, and ordered to pay a yearly tribute of sixty talents, and never to make use either of horses or arms till they had repaid to the temple of Apollo the money they had sacrilegiously carried from thence. Their arms were taken from them, broken to pieces, and burned; and their double voice in the council was taken from them, and given to the Macedonians. Other orders were made for settling the affairs both of religion and the state throughout Greece, all of which were executed by Philip with great exactness and moderation; he paying the most profound respect to the council, and, when he had performed its commands, retiring peaceably with his army back to Macedonia, which gained him great reputation.

At Athens alone the justice and piety of Philip were not understood. The people began to see, though a little too late, that they had been abused and deceived by those who had negociated the late peace. They saw that, through their acceptance of it, the Phocians were destroyed; that Philip, having become master of Thermopylæ, might enter Greece when he pleased; that, in abandoning their allies, they had abandoned themselves; and that, in all probability, they might soon feel the weight of his power, whom they had so foolishly trusted. They therefore began to take new and hostile measures; they ordered that the women should retire out of the villages into the city, that their walls should be repaired, and their forts strengthened. They seemed inclined to question Philip's election into the council of the Amphictyons, because it had been done without their consent; and even to proceed to an open war. In all likelihood, they would have carried things to extravagance, if Demosthenes had not interposed. He told them, that though he was not for making the peace, he was however for keeping it; and that he saw no occasion whatever for their entering into so unequal a contest as would necessarily ensue if they took up arms, not only against Philip, but also against all the states which had concurred with him in the late transactions. This seems to have cooled the rage of the Athenians, and to have brought them to think of ruining Philip gradually, as they had raised him.

The fame of his achievements beyond the bounds of Macedonia having disposed the subjects of Philip to hope every thing from his conduct, and the several states of Greece to desire above all things his friendship, that prudent monarch laid hold of this favourable situation to fix his dominion upon such a stable foundation as that a reverse of fortune should not immediately destroy it. To this end, whilst he carried on his negociations through

Greece, he likewise kept his army in exercise, by taking several places in Thrace, which terribly incommoded the Athenians. Diopithes, who had the government of the Athenian colonies in those parts, perceiving well what end Philip had in view, did not stay for instructions from home, but, having with much expedition raised a considerable body of troops, took advantage of the king's being absent with his army, entered the adjacent territories of Philip, and wasted them with fire and sword.

The king, who, on account of the operations of the campaign in the Chersonesus, was not at leisure to repel Diopithes by force, nor indeed could divide his army without imminent hazard, chose, like an able general, rather to abandon his provinces to insults, which might be afterwards revenged, than, by following the dictates of an ill-timed resentment, to hazard the loss of his veteran army, whereon depended all his hopes. He contented himself, therefore, with complaining to the Athenians of the conduct of Diopithes, who in a time of peace had entered his dominions, and committed such devastations as could scarcely have been justified in a time of war. His partisans supported this application with all their eloquence. They told the Athenians, that unless they recalled Diopithes, and brought him to trial for this infringement of the peace, they ought not to hope either for the friendship of Philip, or that of any other prince or state; neither could they justly complain, if, prompted by such a precedent, others should break faith with them, and fall without the least notice upon their dominions. Demosthenes defended Diopithes, and undertook to show that he deserved the praise and not the censure of the Athenians. Those of the other party began then to charge him with crimes of a different nature; they alleged that he had oppressed the subjects and maltreated the allies of Athens. Demosthenes replied, that of these things there were as yet no proofs; that when such should appear, a single galley might be sent to bring over Diopithes to abide their judgment, but that Philip would not come if they sent a fleet; whence he inferred, that they ought to be cautious, and to weigh well the merits of this cause before they took any resolution. He said, that it was true Philip had not as yet attacked Attica, or pretended to make a descent on their territories in Greece, or to force his way into their ports: when it came to that, he was of opinion they would be hardly able to defend themselves; therefore he thought such men were to be esteemed as sought to protect their frontiers, in order to keep Philip as long as might be at a distance. Upon this he moved, that, instead of disowning what Diopithes had done, or directing him to dismiss his army, they should send him over recruits, and show the king of Macedonia that they knew how to protect their territories, and to maintain the dignity of their state, as well as their ancestors. These arguments had such an effect, that a decree was made conformable to his motion.

Whilst affairs stood thus, the Illyrians, recovering courage, and seeing Philip at such a distance, harassed the frontiers of Macedonia, and threatened a formidable invasion; but Philip, by quick marches, arrived on the borders of Illyricum, and struck this barbarous people with such a panic, that they were glad to compound for their former depredations at the price he was pleased to fix. Most of the Greek cities in Thrace now sought the friendship of the king, and entered into a league with him for their mutual defence. As it cannot be supposed that each of these free cities had a power equal to that of Philip, we may therefore look upon him as their protector. About this time Philip's negociations in the Peloponnesus began to come to light; the Argives and Messenians, growing weary of that tyrannical authority which the Spartans had exercised over them, applied to Thebes for assistance; and the Thebans, out of their natural aversion to Sparta, sought to open a passage for Philip into the Peloponnesus, that, in conjunction with them, he might humble the Lacedæmonians. Philip readily accepted the offer, and resolved to procure a decree from the Amphictyons, directing the Lacedæmonians to leave Argos and Messene free; which, if they complied not with, he, as the lieutenant of the Amphictyons, might, with great appearance of justice, march with a body of troops to enforce their order. When Sparta received intelligence of this, she immediately applied to Athens, earnestly entreating assistance, as in the common cause of Greece. The Argives and Messenians, on the other hand, laboured assiduously to gain the Athenians to their side, alleging that, if they were friends to liberty, they ought to assist those whose only aim was to be free. Demosthenes, at this juncture, outwrestled Philip, if we may borrow that king's expression; for, by a vehement harangue, he not only determined his own citizens to become the avowed enemies of the king, but also made the Argives and Messenians not over fond of him as an ally; which, when Philip perceived, he laid aside all thoughts of this enterprise for the present, and began to practise on Eubœa.

This country, now called *Negropont*, is separated from Greece by the Euripus, a strait so narrow that Eubœa might easily be united to the continent. This situation made Philip call it "the fetters of Greece," which he therefore sought to have in his own hands. There had been for some years great disturbances in that country; under colour of which, Philip sent forces thither, and demolished Porthmos, the strongest city in those parts, leaving the whole country under the government of three lords, whom Demosthenes roundly calls tyrants established by Philip. Shortly after, the Macedonians took Oreus, which was left under the government of five magistrates, also styled tyrants at Athens. Thither Plutarch of Eretria, one of the most eminent persons in Eubœa, went to represent the distresses of his country, and to implore the Athenians to set it free. This suit Demosthenes recommended warmly to the people, who sent thither their famous leader Phocion, supported by formidable votes, but a very slender army; yet so well did he manage the affairs of the commonwealth and her allies, that Philip quickly found he must for a time abandon that project; which, however, he did not until he had formed another no less beneficial to himself, or less dangerous to Athens. It was the prosecution of his conquests in Thrace, which he thought of pushing much further than he had hitherto done, or could be reasonably suspected to have any intention of doing.

Extraordinary preparations were made by the Macedonian monarch for this campaign. His son Alexander was left regent of the kingdom; and he himself with thirty thousand men laid siege to Perinthus, one of the strongest cities in the country. At that time, however, all his arts of cajoling and pretending friendship were insufficient to deceive the Athenians. They gave the command of their army and fleet to Phocion, a general of great abilities, and with whom Philip would have found it very hard to contend. On the other hand, the king of Persia began to turn jealous of the growing power of the Macedonian monarch. The Persian kings had been accustomed to regard those of Macedonia as their faithful allies; but the good fortune of Philip, the continual clamour of the Athenians against him, and his dethroning at pleasure the petty princes of Thrace, made him now be regarded in another light. When, therefore, he led his troops against Perinthus, the Great King, as he was styled by the Greeks, sent his letters mandatory to the governors of the maritime provinces, directing them to supply the place with all things in their power; in consequence of which they filled it with troops, granted subsidies in ready money, and sent besides great convoys of provision and ammunition. The Byzantines also, supposing that their turn would be next, exerted their utmost endeavours for the preservation of Perinthus, sending thither the flower of their youth, with all other necessaries for an obstinate defence. The consequence of all this was, that Philip found himself obliged to raise the siege with great loss.

That the reputation of the Macedonian arms might not sink by this disgrace, Philip made war on the Scythians and Triballi, both of whom he defeated; and then formed a design of invading Attica, though he had no fleet to transport his troops, and knew very well that the Thessalians were not to be depended upon if he attempted to march through the Pisæ, and that the Thebans would even then be ready to oppose his march. To obviate all these difficulties, he had recourse to Athens itself, where, by means of his hired partisans, he procured his old friend Æschines to be sent their deputy to the Amphictyons. This seemed a small matter, and yet was the hinge on which his whole project turned. By the time Æschines had taken his seat, a question was stirred in the council, whether the Locrians of Amphisia had not been guilty of sacrilege in ploughing the fields of Cyrrha in the neighbourhood of the temple of Delphi. The assembly being divided in their opinions, Æschines proposed to take a view of the ground, which was accordingly decreed. But when the Amphictyons came in order to see how things stood, the Locrians, either jealous of their property, or spurred thereto by the suggestions of some who saw farther than themselves, fell upon those venerable persons so rudely, that they were compelled to secure themselves by flight. The Amphictyons decreed that an army should be raised, under the command of one of their own number, to chastise the delinquents; but as this army was to be composed of troops sent from all parts of Greece, the appearance at the rendezvous was so inconsiderable, that the Amphictyons sent to command them durst not undertake anything. The whole matter being reported to the council, Æschines, in a long and eloquent harangue, showed how much the welfare and even the safety of Greece depended on the deference paid to their decrees; and after inveighing against the want of public spirit in such as had not sent their quotas at the time appointed by the council, he moved that they should elect Philip as their general, and pray him to execute their decree. The deputies from the other states, conceiving that by this expedient their respective constituents would be free from any further trouble or expense, agreed to it at once; upon which a decree was immediately drawn up, purporting that ambassadors should be sent to Philip of Macedonia, in the name of Apollo and the Amphictyons, once more to require his assistance, and to notify to him, that the states of Greece had unanimously chosen him their general, with full power to act as he thought fit against such as had opposed the authority of the Amphictyons. Thus of a sudden Philip acquired all that he sought; and having an army ready in expectation of this event, he immediately marched in appearance to execute the commands of the Amphictyons, but in reality to accomplish his own designs; for having passed into Greece with his army, instead of attacking the Locrians, he immediately seized upon Elatea, a great city of Phocis, situated on the river Cephisus.

tle of
ronæa.

The Athenians in the mean time were in the utmost confusion on the news of Philip's march. However, by the advice of Demosthenes, they invited the Thebans to join them against the common enemy of Greece. Philip endeavoured as much as possible to prevent this confederacy from taking place, but all his efforts proved ineffectual. The Athenians raised an army, which immediately marched to Eleusis, where they were joined by the Thebans. The confederates made the best appearance that had ever been seen in Greece, and the troops were exceedingly good; but, unfortunately, the generals were men of no conduct or skill in the military art. An engagement ensued at Cheronæa, in which Alexander commanded one wing of the Macedonian army, and his father Philip the other. The confederate army was divided according to the different nations of which it consisted; the Athenians having the right, and the Bœotians the left. In the beginning of the battle the confederates had the advantage; whereupon Stratocles, an Athenian commander, cried out, "Come on, brother soldiers, let us drive them back to Macedonia," which being overheard by the king, he said very coolly to one of his officers, "These Athenians do not know how to conquer." Upon this he directed the files of the phalanx to be closed up, and retired to a neighbouring eminence, from which, when the Athenians were eager in their pursuit, he rushed down with impetuosity, broke, and routed them with prodigious slaughter. The orator Demosthenes behaved very unbecomingly in this engagement, for he deserted his post, and was one of the first who fled; nay, we are told, that a stake catching hold of his robe, he, not doubting that it was an enemy, ignominiously cried out, "Spare my life."

Philip is appointed general against the Persians.

The victory of Cheronæa determined the fate of Greece; and from this time we must reckon Philip supreme lord of all the Grecian states. The first use he made of his power was to convoke a general assembly, in which he was recognised as generalissimo, and with full power appointed their leader against the Persians. Having, by virtue of his authority, settled a general peace amongst them, and appointed the quota that each of the states should furnish for the war, he dismissed them, and returning to Macedonia, began to make great preparations for this new expedition. His pretence for making war on the Persians at this time was the assistance given by the Persians to the city of Perinthus, as already mentioned. In the mean time, however, the king, by reason of the dissensions which reigned in his family, was rendered quite miserable. He quarrelled with his wife Olympias to such a degree, that he divorced her, and married another woman named Cleopatra. This produced a quarrel between him and his son Alexander, which at length reached to such a height that Alexander retired into Epirus with his mother. Some time afterwards, however, he was recalled, and a reconciliation took place in appearance; but in the mean time a conspiracy was secretly formed against the king's life, the real causes and circumstances of which are very little known. Certain it is, however, that it took effect as the king was exhibiting certain shows in honour of his daughter's marriage with the king of Epirus. Philip having given a public audience to the ambassadors of Greece, went next day in great state to the theatre. All the seats were early occupied; and the shows began with a splendid procession, in which the images of the twelve superior deities of Greece were carried, as also the image of Philip, habited in like manner, as if he now made the thirteenth, at which the people shouted aloud. Then came the king alone, in a white robe, crowned, with his guards at a considerable distance, that the Greeks might see he placed his safety only in his confidence of the loyalty of his subjects. Pausanias, the assassin, however, had fixed himself close by the door of the theatre; and observing that all things fell out as he had foreseen they would, took his opportunity when the king drew near him, and plunging his sword in his left side, laid him dead at his feet. He then fled as fast as he was able towards the place where his horses were, and would have escaped, had not the twig of a vine caught his shoe and thrown him down. This gave time to those who pursued him to come up with him; but instead of securing him, in order to extort a discovery of his accomplices, they put an end to his life.

Character of Philip.

With regard to the character of this monarch, it appears certain that he was one of the most eminent persons that ever sat upon a throne. Had he lived for some time longer, he would in all probability have subdued the Persians; an achievement less difficult than many which he had already accomplished. Had that event taken place, the undertakings of his long and successful reign would have been ennobled and illuminated by the splendour of extensive foreign conquest. Philip would have reached that height of renown which is obtained by the habits of activity, vigilance, and fortitude, in the pursuit of unbounded greatness; and, in the opinion of posterity, would perhaps have surpassed the glory of all kings and conquerors who either preceded or followed him. Yet, even on this supposition, there is not any man of sense and probity, who, if he allows himself time for serious reflection, would purchase the imagined grandeur and prosperity of the king of Macedonia at the price of his artifices and his crimes; and to a philosopher, who considered either the means by which he had obtained his triumphs, or the probable consequences of his dominion over Greece and Asia, the busy ambition of this mighty conqueror would appear but a deceitful scene of splendid misery.

Joy of the Athenians.

No sooner did the news of Philip's death reach Athens, than, as if all danger had been past, the inhabitants showed the most extravagant signs of joy. Demosthenes and his party put on chaplets of flowers, and behaved as if they had gained a great victory. Phocion reproved them for this madness; bidding them remember, that "the army which had beaten them at Cheronæa was lessened but by one." This reproof, however, had very little effect. The people heard with pleasure all the harsh things which the orators could say of the young Alexander, king of Macedonia, whom they represented as a giddy wrong-headed boy, ready to grasp all things in his imagination, and able to perform nothing. The affairs of Macedonia indeed were in a very distracted state on the accession of Alexander; for all the neighbouring nations had the same notion of the young king with the Athenians, and, being irritated by the usurpations of Philip, immediately revolted; and the states of Greece entered into a confederacy against him. The Persians had been contriving how to transfer the war to Macedonia; but as soon as the news of Philip's death reached them, they behaved as if all danger had been terminated. At the same time Attalus, one of the Macedonian commanders, aspired to the crown, and sought to draw off the soldiers from their allegiance.

Alexander declared general of Greece.

In the councils held upon this occasion, Alexander's best friends advised him rather to make use of dissimulation than force, and to try to cajole those whom they thought he could not subdue. These advices, however, were ill suited to the temper of their monarch. He thought that vigorous measures only were proper, and therefore immediately led his army into Thessaly. Here he harangued the princes so effectually, that he thoroughly gained them over to his interest, and was by them declared general of Greece; upon which he returned to Macedonia, where he caused Attalus to be seized and put to death.

In the spring of the next year (335 before Christ), Alexander resolved to subdue the Triballians and Illyrians, who inhabited the countries now called Bulgaria and Sclavonia, and had been very formidable enemies to the Macedonian power. In this expedition he discovered, though then but twenty years of age, a surprising degree of military knowledge. Having advanced to the passes of Mount Hæmus (the Balkan), he learned that the barbarians had posted themselves in the most advantageous manner. Upon the tops of the cliffs, and at the head of every passage, they had placed their carriages and waggons in such a manner as to form a kind of parapet, with their shafts inwards, that when the Macedonians should have half ascended the rock, they might be able to push these heavy carriages down upon them; and they reckoned the more upon this contrivance, because of the close order of the phalanx, which, they imagined, would be terribly exposed by the soldiers wanting room to stir, and thereby to avoid the falling waggons. But Alexander, having directed his heavy-armed troops to march, gave orders, that, where the way would permit, they should open to the right and left, and suffer the carriages to go through; but that, in the narrow passes, they should throw themselves on their faces with their shields behind them, that the carts might run over them. This had the desired effect, and the Macedonians reached the enemy's works without the loss of a man. The dispute was then quickly decided. The barbarians were driven from their posts with great slaughter, and left behind them a considerable booty for the conquerors.

Thebes taken and destroyed.

The next exploits of Alexander were against the Getæ, the Tanlantii, and some other nations inhabiting the country upon the other side of the Danube. These he also overcame; showing in all his actions the most perfect skill in military affairs, joined with the greatest valour. In the mean time, however, all Greece was thrown into commotion by a report which had been confidently spread abroad, that the king was dead in Illyria. The Thebans, on this news, seized Amyntas and Timolaus, two eminent officers in the Macedonian garrison which held their citadel, and dragged them to the market-place, where they were put to death without either form of process, or any crime being alleged against them. Alexander, however, did not suffer them to remain long in their mistake. He marched with such expedition, that in seven days he reached Pallene in Thessaly; and in six days more he entered Bœotia, before the Thebans had any intelligence of his having passed the Straits of Thermopylæ. Even then they would not believe that the king was alive, but insisted that the Macedonian army was commanded by Antipater, or by one Alexander the son of Æropus. The rest of the Greeks, however, were not so hard of belief, and therefore sent no assistance to the Thebans, who were thus obliged to bear the consequences of their own folly and obstinacy. Their city was taken by assault, and the inhabitants were for some hours massacred without distinction of age or sex; after which the houses were demolished, excepting that of Pindar the famous poet, which was spared out of respect to the merit of its owner, and because he had celebrated Alexander king of Macedonia. The lands, except those destined to religious uses, were shared amongst the soldiers, and all the prisoners sold as slaves, by which 440 talents were brought into the king's treasury.

Number of the army with which he invaded Asia.

By this severity the rest of the Grecian states were so thoroughly humbled, that they thought no more of making any resistance, and Alexander had nothing further to hinder him from pursuing his favourite project of invading Asia. Very little preparation was necessary for the Macedonian monarch, who went as to an assured conquest, and reckoned upon being supplied chiefly by the spoils of his enemies. Historians are not agreed as to the number of his army. Arrian says, that there were thirty thousand foot and five thousand horse. Diodorus Siculus informs us that there were thirteen thousand Macedonian foot, seven thousand of the confederate states, and five thousand mercenaries, under the command of Parmenio. Of the Odrisians, Triballians, and Illyrians, there were five thousand; and of the Agrians, who were armed only with darts, one thousand. As for the horse, he tells us there were eighteen hundred commanded by Philotas, and as many Thessalians under the command of Callas. Out of the confederate states of Greece there were six hundred commanded by Eurygius; and nine hundred Thracians and Pæonians, who led the van under Cassander. Plutarch tells us, that, according to a moderate computation, Alexander had thirty thousand foot and five thousand horse; and that, according to the largest estimate, he had thirty-four thousand foot and four thousand horse. As to his fund for the payment of the army, Aristobulus says it was but seventy talents; and Onesicritus, who was also present in this expedition, not only takes away the seventy talents, but affirms that the king was two hundred in debt. As for provisions, there was just sufficient for a month and no more; and to prevent disturbances, Antipater was left in Macedonia with twelve thousand foot and fifteen hundred horse.

The army having assembled at Amphipolis, Alexander marched thence to the mouths of the river Strymon; then crossing Mount Pangæus, he took the road to Abdera. Crossing the river Ebrus, he proceeded through the country of Pætis, and in twenty days reached Sestos; thence he marched to Eleus, where he sacrificed on the tomb of Protesilaus, because he was the first amongst the Greeks who at the siege of Troy set foot upon the Asiatic shore. He did this, that his landing might be more propitious than that of the hero to whom he sacrificed, who was soon afterwards slain. The greatest part of the army, under the command of Parmenio, embarked at Sestos, on board of a fleet of a hundred and sixty galleys of three benches of oars, besides small craft. Alexander himself sailed from Eleus; and when he was in the middle of the Hellespont, offered a bull to Neptune and the Nereids, pouring forth at the same time a libation from a golden cup. When he drew near to the shore, he launched a javelin, which stuck in the earth; then, in complete armour, he leaped upon the strand; and having erected altars to Jupiter, Minerva, and Hercules, he proceeded to Ilium. Here again he sacrificed to Minerva; and taking down some arms which had hung in the temple of that goddess since the time of the Trojan war, he consecrated his own in their stead. He sacrificed also to the ghost of Priam, to avert his wrath on account of the descent which he himself claimed from Achilles.

In the mean time the Persians had assembled a great army in Phrygia, amongst whom was one Memnon, a Rhodian, the best officer in the service of Darius. Alexander, as soon as he had performed all the ceremonies which he judged necessary, marched directly towards the enemy. Memnon gave it as his opinion that they should burn and destroy all the country round, that they might deprive the Greeks of the means of subsisting, and then transport a part of their army into Macedonia. But the Persians, depending on their cavalry, rejected this salutary advice, and posted themselves along the river Granicus, in order to await the arrival of Alexander. In the engagement which ensued on the banks of that river, the Persians were defeated, and Alexander became master of all the neighbouring country, which he immediately began to take care of, as if it had been part of his hereditary dominions. The city of Sardis was immediately delivered up; and here Alexander built a temple to Jupiter Olympius. After this, he restored the Ephesians to their liberty, ordered the tribute which they formerly paid to the Persians to be applied towards the rebuilding the magnificent temple of Diana, and having settled the affairs of the city, marched against Miletus. This place was defended by Memnon with a considerable body of troops who had fled thither after the battle of Granicus, and therefore made a vigorous resistance. The fortune of Alexander, however, prevailed; and the city was soon reduced, though Memnon with part of the troops escaped to Halicarnassus. After this, the king dismissed his fleet; a proceeding for which various causes have been assigned, though it is probable, that the chief reason was to show his army that their only resource now lay in subverting the Persian empire.

Almost all the cities between Miletus and Halicarnassus submitted as soon as they heard that the former was taken; but Halicarnassus, where Memnon commanded with a very numerous garrison, made an obstinate defence. Nothing, however, was capable of resisting the Macedonian army. Memnon was at last obliged to abandon the place; upon which Alexander took and razed the city of Tralles in Phrygia, received the submission of several princes tributary to the Persians; and having destroyed the Marmarians, a people of Lycia who had fallen upon the rear of his army, put an end to the campaign; after which he sent home all the new married men, in obedience, it would seem, to a precept of the Mosaic law, and which endeared him more to his soldiers than almost any other action of his life.

As soon as the season would permit, Alexander quitted the province of Phaselus; and having sent part of his army through the mountainous country to Perga, by a short but difficult road, took his route by a certain promontory, where the way is altogether impassable except when the north winds blow. At the time of the king's march the south wind had held for a long time; but of a sudden it changed, and blew from the north so violently, that, as he and his followers declared, they obtained a safe and easy passage, through divine assistance. By many this march is considered as miraculous, and compared to that of the children of Israel through the Red Sea; whilst, on the other hand, it is the opinion of others, that there was nothing at all extraordinary in it. He continued his march towards Gordium, a city of Phrygia; the enemy having abandoned the strong pass of Telmissus, through which it was necessary for him to march. When he arrived at Gordium, and found himself under the necessity of staying there some time till the several corps of his army could be re-united, he expressed a strong desire of seeing Gordius's chariot, and the famous knot in the harness, of which such strange stories had been published to the world. The cord in which this knot was tied was made of the inner rind of the cornel tree; and no eye could perceive where it began or ended. Alexander, when he could find no possible way of untying, and yet was unwilling to leave it tied, lest it should cause some fears in the breasts of his soldiers, is said by some authors to have cut the cords with his sword, saying "it matters not how it is undone." But Aristobulus assures us, that the king wrested a wooden pin out of the beam of the waggon, which, being driven in across the beam, held it up, and so took the yoke from under it. Be this as it may, however, Arrian informs us, that a great tempest of thunder, lightning, and rain, happening the succeeding night, it was held declarative of the true solution of this knot, and that Alexander would become master of Asia.

Alexander's sickness and recovery.

The king having left Gordium, marched towards Cilicia, where he was attended with his usual good fortune, the Persians abandoning all the strong passes as he advanced. As soon as he entered the province, he received advice that Arsames, whom Darius had made governor of Tarsus, was about to abandon it, and that the inhabitants were very apprehensive that he intended to plunder them before he withdrew. To prevent this, the king marched incessantly, and arrived just in time to save the city. But his saving it had well nigh cost him his life; for, either through the excessive fatigue of marching, as some say, or, according to others, by his plunging when very hot into the river Cydnus, which, as it runs through thick shades, has its waters excessively cold, he fell into such a distemper as threatened immediate dissolution. His army lost their spirits; the generals, perplexed, knew not what to do; and his physicians were so much affrighted, that the terror of his death hindered them from using the necessary methods for preserving his life. Philip the Acarnanian alone preserved self-command enough to examine the nature of the king's disease, the worst symptom of which was a continual shivering, which he removed by means of a potion, and in a short time the king recovered his usual health.

Battle of Issus.

Soon after Alexander's recovery, he received the agreeable news that Ptolemy and Asander had defeated the Persian generals, and made great conquests on the Hellespont; and a little after that he met the Persian army at Issus, commanded by Darius himself. A bloody engagement ensued, in which the Persians were defeated with great slaughter. The consequences of this victory were very advantageous to the Macedonians. Many governors of provinces, and petty princes, submitted themselves to the conqueror; and such as did so were treated, not as a newly conquered people, but as his old hereditary subjects, being neither burdened with soldiers nor oppressed with tribute. Amongst the number of those places which, within a short space after the battle of Issus, sent deputies to submit to the conqueror, was the city of Tyre. The king, whose name was Azelmicus, was absent in the Persian fleet; but his son was amongst the deputies, and was very favourably received by Alexander. The king probably intended to confer particular honours upon the city of Tyre, for he acquainted the inhabitants that he would come and sacrifice to the Tyrian Hercules, the patron of their city, to whom they had erected a most magnificent temple. But these people, like most other trading nations, were far too suspicious to think of admitting such an enterprising prince with his troops within their walls. They therefore sent their deputies again to him to inform him that they were ready to do whatever he should command them; but as to his coming and sacrificing in their city, they could not consent to that, but were positively determined not to admit a single Macedonian within their gates. Alexander immediately dismissed their deputies in great displeasure. He then assembled a council of war, in which he insisted strongly on the disaffected state of Greece (for most of the Grecian states had sent ambassadors to Darius, to enter into a league with him against the Macedonians), the power of the Persians by sea, and the folly of carrying on the war in distant provinces, whilst Tyre was left unreduced behind them; he also remarked, that if once this city was subdued, the sovereignty of the sea would be transferred to them, because it would fix their possession of the coasts; and as the Persian fleet was composed chiefly of tributary squadrons, those tributaries would fight the battles, not of their late, but of their present masters.

Tyre taken and destroyed.

For these reasons the siege of Tyre was resolved on. The town was not taken, however, without great difficulty; which provoked Alexander to such a degree that he treated the inhabitants with the greatest cruelty. (See TYRE.) After the reduction of Tyre, Alexander, though the season was already far advanced, resolved to make an expedition into Syria; and in his way thither proposed to chastise the Jews, who had highly offended him during the siege of Tyre; for when he sent to them to demand provisions for his soldiers, they answered, that they were the subjects of Darius, and bound by oath not to supply his enemies. The king, however, was pacified by their submission, and not only pardoned them, but conferred many privileges upon them.

Egypt submits.

From Jerusalem Alexander marched directly to Gaza, the only place in that part of the world which still held out for Darius. This was a very large and strong city, situated upon a very high hill, about five miles from the sea-shore. One Batis or Betis, an eunuch, had the government of the place, and had made every preparation necessary for sustaining a long and obstinate siege. The governor defended the place with great valour, and several times repulsed his enemies; but at last it was taken by storm, and all the garrison slain to a man; and this secured to Alexander an entrance into Egypt, which having before been very impatient of the Persian yoke, admitted the Macedonians peaceably. Here the king laid the foundations of the city of Alexandria, which for many years afterwards continued to be the capital of the country. Whilst he remained here, he also formed the singular design of visiting the temple of Jupiter Ammon. As to the motives by which he was induced to take this extraordinary journey, authors are not agreed; but certain it is, that he hazarded himself and his troops in the highest degree, there being two dangers in this march, which, with the example before him of Cambyses, who lost the greater part of his army in it, might have terrified any body but Alexander. The first was the want of water, which, in the sandy deserts surrounding the temple, is nowhere to be found; the other, the uncertainty of the road from the fluctuation of the sands, which, changing their situation every moment, leave the traveller neither a road to walk in, nor a mark to march by. These difficulties, however, Alexander overcame, though not without a miraculous interposition, as is pretended by all his historians.

Battle of Arbela.

Alexander having consulted the oracle, and received a favourable answer, returned to pursue his conquests. Having settled the government of Egypt, he appointed the general rendezvous of his forces at Tyre. Here he met with ambassadors from Athens, requesting him to pardon such of their countrymen as he found serving the enemy. The king, being desirous to oblige such a famous state, granted their request; and also sent a fleet to the coast of Greece, to prevent the effects of some commotions which had lately happened in Peloponnesus. He then directed his march to Thapsacus; and having passed the Euphrates and Tigris, met with Darius near Arbela, where the Persians were again overthrown with prodigious slaughter, and by this victory Alexander became in effect master of the Persian empire.

Babylon, Susa, and Persepolis, reduced.

After this important victory, Alexander marched directly to Babylon, which was immediately delivered up; the inhabitants being greatly disaffected to the Persian interest. After thirty days' stay in this country, the king marched to Susa, which had already surrendered to Philoxenus; and here he received the treasures of the Persian monarch, amounting, according to the most generally received account, to fifty thousand talents. Having received also at this time a supply of six thousand foot and five hundred horse from Macedonia, he set about reducing the nations of Media, amongst whom Darius had retired. He first reduced the Uxians, and having forced a passage to Persepolis, the capital of the empire, he, like a barbarian, destroyed the stately palace there, a pile of building not to be equalled in any part of the world; after having given up the city to be plundered by his soldiers. In the palace he found one hundred and twenty thousand talents, which he appropriated to his own use, and caused immediately to be carried away upon mules and camels; for he had such an extreme aversion to the inhabitants of Persepolis, that he determined to leave nothing valuable in that city.

Alexander pursues Darius, who is murdered by Bessus.

During the time that Alexander remained at Persepolis, he received intelligence that Darius remained at Ecbatana, the capital of Media; upon which he pursued him with the greatest expedition, marching at the rate of nearly forty miles a day. In fifteen days he reached Ecbatana, where he was informed that Darius had retired from thence five days before, with an intent to pass into the remotest provinces of his empire. This put some stop to the rapid progress of the Macedonian army; and the king perceiving that there was no necessity for hurrying himself and his soldiers in such a manner, began to give the orders requisite in the present situation of his affairs. The Thessalian horse, who had deserved exceedingly well of him in all his battles, he dismissed according to his agreement; gave them their whole pay, and ordered two thousand talents over and above to be distributed amongst them. He then declared that he would force no man; but if any were willing to serve him longer for pay, he desired that they would enter their names in a book, which a great many of them did, whilst the rest sold their horses, and prepared for their departure. The king appointed Epocillus to conduct them to the sea, and assigned him a body of horse as an escort: he likewise sent Menetes with them, to take care of their embarkation, and see that they were safely landed in Eubœa, without any expense to themselves.

On receiving fresh information concerning the state of Darius's affairs, the king again set out in pursuit of him, advancing as far as Rhages, a city one day's journey from the Caspian Straits. There he understood that Darius had some time before passed those straits; and this information leaving him again without hopes, he halted for five days. Oxidates, a Persian whom Darius had left prisoner at Susa, was made governor of Media, whilst the king departed on an expedition into Parthia. The Caspian Straits he passed immediately without opposition, and then gave directions to his officers to collect a quantity of provisions sufficient to serve his army on a long march through a wasted country. But before his officers could accomplish these commands, the king received intelligence that Darius had been murdered by one of his own subjects, Bessus, the governor of Bactria.

As soon as Alexander had collected his forces together, and settled the government of Parthia, he entered Hyrcania; and having, according to his usual custom, committed the greater part of his army to the care of Craterus, he, at the head of a choice body of troops, passed through certain craggy roads, and, before the arrival of Craterus, who took an open and easy path, struck the whole provinces with such terror, that all the principal places were immediately put into his hands; and soon afterwards the province of Aria also submitted, and the king continued Satibarzanes the governor in his employment. The reduction of this province completed the conquest of Persia; but the ambition of Alexander to become master of every nation of which he had the least intelligence, induced him to enter the country of the Mardi, merely because its rocks and barrenness had hitherto prevented any one from conquering, or indeed from attempting to conquer it. This conquest, however, he easily accomplished, and obliged the whole nation to submit to his pleasure. But in the mean time disturbances began to arise in Alexander's new empire, and amongst his troops, which all his activity could not thoroughly suppress. He had scarcely left the province of Aria, when he received intelligence that the traitor Bessus had caused himself to be proclaimed king of Asia by the name of Artaxerxes; and that Satibarzanes had joined him, after having massacred all the Macedonians who had been left in the province. Alexander appointed one Arsames governor in the room of Satibarzanes, and marched thence with his army against the Zarangæ, who, under the command of Barzaentes, one of those who had conspired against Darius, had taken up arms, and threatened to make an obstinate defence. But their numbers daily decreasing, Barzaentes, afraid that they would purchase their own safety at the expense of his, privately withdrew from his camp, and, crossing the river Indus, sought shelter amongst the nations beyond it. But they, either dreading the power of Alexander, or detesting the treachery of this Persian towards his former master, seized and delivered him up to Alexander, who immediately caused him to be put to death.

The Macedonians give themselves up to pleasure.

The immense treasure which the Macedonians had acquired in the conquest of Persia now began to affect their discipline. The king himself was of a most generous disposition, and liberally bestowed his gifts on those around him; but they made a bad use of his bounty, and foolishly indulged in those vices by which the former possessors of that wealth had lost it. The king did all in his power to discourage the lazy and inactive pride which now began to show itself amongst his officers; but neither his discourses nor his example had any considerable effect. The manners of his courtiers from bad became worse, in spite of all he could say or do to prevent it; and at last they proceeded to censure his conduct, and to express themselves with some bitterness on the subject of his long continuance of the war, and his leading them constantly from one labour to another. This rose to such a height that the king was at last obliged to use some severity, in order to keep his army within the limits of their duty. From this time forward, however, Alexander himself began to alter his conduct, and, by yielding a little to the customs of the orientals, endeavoured to secure that obedience on the part of his new subjects which he found so difficult to preserve amongst his old ones. He likewise endeavoured, by various methods, to blend the customs of the Asiatics and the Greeks. The form of his civil government resembled that of the ancient Persian kings; in military affairs, however, he strictly preserved the Macedonian discipline; but then he made choice, out of the provinces, of thirty thousand boys, whom he caused to be instructed in the Greek language, and directed to be brought up in such a manner as that from time to time he might with them recruit the phalanx. The Macedonians observed with great concern these extraordinary measures, which suited very ill with their gross understandings; for, after all the victories they had gained, they expected to be absolute lords of Asia, and to possess not only the riches of its inhabitants, but to rule the inhabitants themselves; whereas they now found that Alexander meant no such thing, but that, on the contrary, he conferred governments, offices at court, and all other marks of confidence and favour, indiscriminately both on Greeks and Persians. From this time also the king seems to have given proofs of a cruelty which he had never shown before. Philotas, his most intimate friend, was seized, tortured, and put to death, for a conspiracy of which it could never be proved that he was guilty; and soon afterwards Parmenio and some others were executed without any crime at all, real or alleged. These things very much disturbed the army. Some of them wrote home to Macedonia respecting the king's suspicions of his friends, and his disposition to hunt out enemies at the very extremities of the world. Alexander having intercepted some of these letters, and procured the best information he could concerning their authors, picked out these dissatisfied people, and having disposed them into a corps, gave it the title of the "turbulent battalion;" hoping by this means to prevent the spirit of disaffection from pervading the whole army. As a further precaution against any future conspiracy, Alexander thought fit to appoint Hephæstion and Clytus generals of the auxiliary horse; being apprehensive, that if this authority was lodged in the hands of a single person, it might prompt him to dangerous undertakings, and at the same time furnish him with the means of carrying them into execution. To keep his forces in action, he suddenly marched into the country of the Euergetæ, or Benefactors, and found them full of the kind and hospitable disposition for which that name had been bestowed on their ancestors; he therefore treated them with great respect, and at his departure added some lands to their dominions, which lay contiguous, and which for that reason they had requested of him.

Satibarzanes defeated and killed.

Turning next to the east, he entered Arachosia, the inhabitants of which submitted without giving him any trouble. Whilst he passed the winter in these parts, the king received advice that the Arians, whom he had so lately subdued, were up again in arms, Satibarzanes having returned into that country with two thousand horse which had been assigned him by Bessus. Alexander instantly despatched Artabazus the Persian, with Erigyus and Caranus, two of his commanders, and a considerable body of horse and foot; he likewise ordered Phrataphernes, to whom he had given the government of Parthia, to accompany them. A general engagement ensued, in which the Arians behaved very well as long as their commander Satibarzanes lived; but he engaging Erigyus, the Macedonian struck him first in the throat, and then, drawing forth his spear again, through the mouth, so that he immediately expired, and with him the courage of his soldiers, who instantly began to fly; whereupon Alexander's commanders made an easy conquest of the rest of the country, and effectually reduced it under his obedience.

The king, notwithstanding the inclemency of the season, advanced into the country of Paropamisus, so called from the mountain Paropamisus, which the soldiers of Alexander called Caucasus. Having crossed the country in sixteen days, he came at length to an opening leading into Media; and finding it of a sufficient breadth, he directed a city to be built there, which he called Alexandria, as also several other towns about a day's journey distant from thence; and in these places he left seven thousand persons, part of them such as had hitherto followed his camp, and part of the mercenary soldiers, who, weary of continual fatigue, were content to dwell there. Having thus settled things in this province, sacrificed solemnly to the gods, and appointed Proexes the Persian president thereof, with a small body of troops under the command of Niloxenus to assist him, he resumed his former design of penetrating into Bactria.

Bessus reduced and put to death.

Bessus, who had assumed the name of Artaxerxes, when he was assured that Alexander was marching towards him, immediately began to waste all the country between Paropamisus and the river Oxus, which river he passed with all his forces, and then burned all the vessels he had made use of for transporting them, retiring to Nautaca, a city of Sogdia; fully persuaded that, by the precautions he had taken, Alexander would be compelled to give over his pursuit. This conduct of his, however, disheartened his troops, and gave the lie to all his pretensions; for he had affected to censure Darius's conduct, and had charged him with cowardice, in not defending the rivers Euphrates and Tigris, whereas he now quitted the banks of the most defensible river perhaps in the whole world. As to his hopes, though it cannot be said they were ill founded, yet they proved absolutely vain; for Alexander, continuing his march, notwithstanding the hardships his soldiers sustained, reduced all Bactria under his obedience, particularly the capital Bactria and the strong castle Aornus. In the latter he placed a garrison under the command of Archelaus, but the government of the province he committed to Artabazus. He then continued his march to the river Oxus, on the banks of which when he arrived, he found it three quarters of a mile in breadth, its depth more than proportional to its breadth, its bottom sandy, its stream so rapid as to render it almost unnavigable, and neither boat nor tree in its neighbourhood; so that the ablest commanders in the Macedonian army were of opinion that the army would be obliged to march back. The king, however, having first sent away, under a proper escort, all his infirm and worn-out soldiers, that they might be conducted safely to the sea-ports, and thence transported to Greece, devised a method of passing this river without either boat or bridge, by causing the hides which covered the soldiers' tents and carriages to be stuffed with straw, and then tied together, and thrown into the river. Having crossed the Oxus, he marched directly towards the camp of Bessus, where, when he arrived, he found it abandoned; but at the same time received letters from Spitamenes and Dataphernes, who were the chief commanders under Bessus, signifying, that if he would send a small party to receive Bessus, they would deliver him into his hands; which they did accordingly, and the traitor was immediately put to death.

Alexander passes the Indus.

A supply of horses having now arrived, the Macedonian cavalry were remounted. Alexander continued his march to Maracanda, the capital of Sogdia, whence he advanced to the river Iaxartes. Here he performed extraordinary exploits against the Scythians, from whom, however, though he overcame them, his army suffered much; and the revolted Sogdians, being headed by Spitamenes, gave him a great deal of trouble. Here also he married Roxana the daughter of Oxyartes, a prince of the country whom he had subdued. But during these expeditions, the king greatly disgusted his army by the murder of his friend Clytus in a drunken quarrel at a banquet, and by his extravagant vanity in claiming divine honours. At last he arrived at the river Indus, where Hephæstion and Perdiccas had already provided a bridge of boats for the passage of that river. The king refreshed his troops for thirty days in the countries on the other side of the river, which were those of his friend and ally Taxiles, who gave him thirty elephants, and joined his army with about seven hundred Indian horse, to which, when they were to enter upon action, he afterwards added five thousand foot. The true reason of this seems to have been his enmity to Porus, an Indian prince whose territories were situated on the other side of the river Hydaspes. During this recess, the king sacrificed with great solemnity; receiving also ambassadors from Ambisurus, a very potent prince, and from Doxareas, who was likewise a king in those parts, with tenders of their duty, and considerable presents. When these ceremonies were ended, Alexander appointed Philip governor of Taxila, and put a Macedonian garrison into the place, because he intended to erect an hospital there for the cure of his sick and wounded soldiers. He then ordered the vessels of which his bridge had been composed when he passed the Indus to be taken to pieces, that they might be brought to the Hydaspes, where he was informed that Porus with a great army lay encamped to dispute his passage. When he approached the banks of this river with his army, and the auxiliaries under the command of Taxiles, he found that the people he had to do with were not so easily to be subdued as the Persians and other Asiatics. The Indians were not only a very tall and robust, but also a very hardy and well-disciplined people; and their king Porus was a prince of high spirit, invincible courage, and superior ability.

Passage of the Hydaspes with difficulty.

It was about the summer solstice when Alexander reached the Hydaspes, and consequently its waters were broader, deeper, and more rapid, than at any other time; for in India the rivers swell as the sun's increasing heat melts the snow, and subside again as winter approaches. Alexander therefore had every difficulty to struggle with. Porus had made his dispositions so judiciously, that Alexander found it impossible to practise upon him as he had done upon others, and to pass the river in his view; wherefore he was constrained to divide his army into small parties, and to employ other arts, in order to get the better of so vigilant a prince. To this end he caused a great quantity of corn and other provisions to be brought into his camp, giving out that he intended to remain where he was till the river should subside, and, by becoming fordable, afford him an opportunity of forcing a passage. This did not, however, prevent Porus from keeping up very strict discipline in his camp; which Alexander perceiving, frequently made such motions as seemed to indicate a change of his resolution, and that he had still thoughts of passing the river. The main thing the Macedonians stood in fear of were the elephants; for the bank being pretty steep on the other side, and it being the nature of horses to start at the first appearance of these animals, it was foreseen that the army would be disordered, and incapable of sustaining the charge of Porus's troops. At length Alexander passed the river by the following contrivance. At the distance of a hundred and fifty stadia from his camp there was a rocky promontory projecting into the river, thickly covered with wood; and over against this promontory there lay a pretty large uninhabited island, almost overgrown with trees. The king therefore conceived within himself a project of conveying a body of troops from this promontory into that island; and upon this scheme he built his hopes of surprising Porus, vigilant as he was. To this end he kept him and his army constantly alarmed for many nights together, till he perceived that Porus apprehended that it was only done to harass his troops, and therefore no longer drew out of his camp, but trusted to his ordinary guards; then Alexander resolved to put his design in execution. A considerable body of horse, the Macedonian phalanx, with some corps of light-armed foot, he left in his camp under the command of Craterus, as also the auxiliary Indians, giving orders that if Porus marched against him with part of his army, and left another part with the elephants behind in his camp, Craterus and his forces should remain where they were; but if it so happened that Porus withdrew his elephants, then Craterus was to pass the river, because his cavalry might then do so with safety. Alexander having marched half the way, or about nine of our miles, ordered the mercenary troops under the command of Attalus and other generals to remain there, and directed them, that as soon as they knew he was engaged with the Indians on the other side, they should pass in vessels provided for that purpose, in order to assist him. Then marching a long way about, that the enemy might not perceive his design of reaching the rock, he advanced as diligently as he could towards that post. It happened very fortunately for him, that a great storm of thunder, lightning, and hail, rose in the night, whereby his march was perfectly concealed, his vessels of thirty oars put together, and his tents stuffed and stitched, so that they passed from the rock into the island without being perceived, a little before break of day, the storm ceasing just as he and his soldiers were ready for their passage. When they had traversed the island, they boldly set forward to gain the opposite shore in sight of Porus's outposts, who instantly hastened to give their master an account of the attempt. Alexander landed first himself, and was followed as expeditiously as possible by his forces, whom he took care to draw up as fast as they arrived. When they began their march again, they found that their good fortune was not so great as they at first esteemed it; for it appeared now that they had not reached the continent at all, but were in truth in another island much larger than the former. They crossed it as fast as they could, and found that it was divided from the *terra firma* by a narrow channel, which, however, was so swelled by the late heavy rain, that the poor soldiers were obliged to wade up to the breast. When they were on the other side, the king drew them up again carefully, ordering the foot, in number about six thousand, to march slowly, whilst himself, with five thousand horse, led the advance. As soon as Porus received intelligence that Alexander was actually passing the river, he sent his son with two thousand horse and a hundred and twenty armed chariots to oppose him. But they came too late; Alexander had already reached the shore, and begun his march.

When the Macedonian scouts perceived them advance, they informed the king, who sent a detachment to attack them, remaining still at the head of his cavalry in expectation of Porus. But when he found that this party was unsupported, he instantly attacked with all his horse, and defeated them with the slaughter of many, and the loss of all their armed chariots, the son of Porus being slain in the fight. The remainder of the horse returning to the camp with this disastrous account, Porus was in some confusion; he however quickly adopted the best and wisest resolutions which circumstances would allow, namely, to leave a part of his army, with some of his elephants, to oppose Craterus, who was now about to pass the river also, and with the remainder to march against Alexander and his forces, who were already passed. This resolution once taken, he marched immediately out of his camp at the head of four thousand horse, thirty thousand foot, three hundred chariots, and two hundred elephants. He advanced as expeditiously as he could, till he came into a plain which was firm and sandy, where his chariots and elephants might act to advantage; and there he halted, that he might put his army in order, knowing well that he need not go in quest of his enemy. Alexander soon came up with his horse, but he did not charge Porus; on the contrary, he halted, and put his troops in order, that they might be able to defend themselves in case they were attacked. When he had waited some time, his foot arrived, and he immediately surrounded them with his horse, that, after so fatiguing a march, they might have time to cool and breathe a little before they were led to engage. Porus permitted all this, because it was not his interest to fight, and because he depended chiefly upon his order of battle, the elephants covering his foot, so that the Macedonians could not charge them.

Porus himself defeated.

When Alexander had disposed his foot in proper order, he placed his horse on the wings; and, observing that he was much superior in that arm to the enemy, and that the cavalry of Porus were easy to be charged, he resolved to let the foot have as little share as possible in the battle. To this end, having given the necessary directions to Cœnus, who commanded them, he went himself to the right, and fell with great fury upon the left wing of Porus. The dispute, though short, was very bloody. The cavalry of Porus, though they fought gallantly, were quickly broken; and the foot being by this means uncovered, the Macedonians charged them. The Indian horse rallying, came up to their relief; but they were again defeated. By this time the archers had wounded many of the elephants, and killed most of their riders, so that they did not prove less troublesome and dangerous to their own side than to the Macedonians; whence a great confusion ensued, and Cœnus, taking this opportunity, fell on with the troops under his command, and entirely defeated the Indian army. Porus himself behaved with the greatest intrepidity, and with the most excellent conduct; he gave his orders, and directed every thing, as long as his troops retained their formation; and when they were broken, he retired from party to party as they made stands, and continued fighting till every corps of Indians was put to the route. In the mean time Craterus had passed with the rest of the Macedonian army; and these, falling upon the flying Indians, increased the slaughter of the day excessively, insomuch that twenty thousand foot and three thousand horse were killed, all the chariots were hacked to pieces, and the elephants not killed were taken; two of Porus's sons fell here, as also most of his officers of all ranks.

As for Porus, Alexander gave strict directions that no injury might be done to his person. He even sent Taxiles to persuade him to surrender himself, and to assure him that he should be treated with all the kindness and respect imaginable; but Porus, disdaining this advice from the mouth of an old enemy, threw a javelin, which would have killed him, but for the quick turn of his horse. Meroe the Indian, who was in the service of Alexander, succeeded better. He had been the old acquaintance of Porus, and therefore when he entreated that prince to spare his person, and to submit himself to fortune and a generous victor, Porus followed his advice; and we may truly say, that the condition of this Indian king suffered nothing by the loss of the battle. Alexander immediately gave him his liberty, and shortly afterwards restored him to his kingdom, to which he annexed provinces almost equal to it in value. Neither was Alexander a loser by his munificence, for Porus remained his true friend and constant ally. To perpetuate the memory of this victory, Alexander ordered two cities to be erected; one on the field of battle, which he named Nicæa; the other on the opposite side of the river, which he called Bucephala, in honour of his horse Bucephalus, who died here, as Arrian says, of mere old age, being on the verge of thirty. All the soldiers who fell in the battle he buried with great honours, offered solemn sacrifices to the gods, and exhibited pompous shows on the banks of the Hydaspes, where he had forced his passage. He then entered the territories of the Glausæ, in which were thirty-seven good cities, and a multitude of populous villages. All these were delivered up to him without fighting; and as soon as he received them, he presented them to Porus, and having reconciled him to Taxiles, he sent the latter home to his own dominions. About this time ambassadors arrived from several Indian princes with their submissions; and Alexander having conquered the dominions of another Porus, which lay on the Hydraotes, a branch of the Indus, added them to those of Porus his ally.

Sangala taken and razed.

In the middle of all this success, however, news arrived that the Cathei, Oxydracæ, and the Malli, the most warlike nations of India, were confederated against the Macedonians, and had drawn together a great army. The king immediately marched to give them battle, and in a few days reached a city called Sangala, seated on the top of a hill, and having a fine lake behind it. Before this city the confederate Indians lay encamped, having three circular lines of carriages locked together, and their tents pitched in the centre. Notwithstanding the apparent difficulty of forcing these intrenchments, Alexander resolved immediately to attack them. The Indians made a noble defence; but at last the first line of their carriages was broken, and the Macedonians entered. The second was stronger by far; yet Alexander attacked that too, and after a desperate resistance forced it. The Indians, without trusting to the third, retired into the city, which Alexander would have invested; but the foot he had with him not being sufficient for that purpose, he caused his works to be carried on both sides as far as the lake; and, on the other side of that, ordered several brigades of horse to take post, ordering also battering engines to be brought up, and in some places employing miners. The second night, he received intelligence that the besieged, knowing the lake to be fordable, intended to make their escape through it. Upon this the king ordered all the carriages which had been taken in forcing their camp, to be placed up and down the roads, in hopes of preventing their flight; giving directions to Ptolemy, who commanded the horse on the other side of the lake, to be extremely vigilant, and to cause all his trumpets to sound, that the forces might repair to that post where the Indians made their greatest effort. These precautions had all the effect that could be desired; for of the few Indians who got through the lake, and passed the Macedonian horse, the greater part were killed on the roads; but the greatest part of their army was constrained to retire again through the water into the city. Two days after, the place was taken by storm. Seventeen thousand Indians were killed, and seventy thousand taken prisoners, with three hundred chariots, and five hundred horse. The Macedonians are said to have lost only a hundred men in this siege; but they had twelve hundred wounded, and amongst these several persons of great distinction. The city was no sooner taken, than Alexander despatched Eumenes his secretary, with a party of horse, to acquaint the inhabitants of the cities adjacent with what had befallen the Sangalans; promising also, that they should be kindly treated if they would submit. But they were so much affrighted at what had happened to their neighbours, that, abandoning all their cities, they fled into the mountains; choosing rather to expose themselves to wild beasts than to these invaders, who had treated their countrymen so cruelly. When the king was informed of this, he sent detachments of horse and foot to scour all the roads; and these, finding aged, infirm, and wounded people, to the number of about five hundred, put them to the sword without mercy. Perceiving that it was impossible to persuade the inhabitants to return, he caused the city of Sangala to be razed, and gave the territories to the few Indians who had submitted to him.

The troops refuse to proceed farther.

Alexander, still unsated with conquest, now prepared to pass the Hyphasis. The chief reason which induced him to think of this expedition, was the information he had received of the state of the countries beyond that river. He was told that they were in themselves rich and fruitful; that their inhabitants were not only a very martial people, but very civilized; that they were governed by the nobility, who were themselves subject to the laws; and that as they lived in happiness and freedom, it was likely they would fight obstinately in defence of those blessings. He was further told, that amongst these nations there were the largest, strongest, and most useful elephants bred and tamed; and was therefore fired with an earnest desire of reducing such a bold and brave people under his rule, and of attaining to the possession of the many valuable things that were said to be amongst them. As exorbitant, however, as his personal ambition was, he found it impossible to infuse any part of it into the minds of his soldiers, who were so far from wishing to triumph over new and remote countries, that they were highly desirous of leaving those that they had already conquered. When therefore they were informed of the king's intentions, they privately consulted together in the camp about the situation of their own affairs. At this consultation, the gravest and best of the soldiers lamented that they were made use of by their king, not as lions, who fall fiercely upon those who have injured them, but as mastiffs, who fly upon and tear those who are pointed out to them as enemies. The rest were not so modest, but expressed themselves roundly against the king's humour for leading them from battle to battle, from siege to siege, and from river to river; protesting that they would follow him no farther, nor lavish their blood any longer, to purchase for him the fame he coveted. Alexander had too much penetration not to perceive that his troops were very uneasy. He therefore harangued them from his tribunal; but though his eloquence was great, and the love his army had for him was yet very strong, they did not relent. For some time the soldiers remained sullen and silent; and at last turned their eyes on Cœnus, an old and experienced general, whom Alexander loved, and in whom the army put great confidence. He had the generosity to undertake their cause, and told Alexander frankly, "that men endured toil in hopes of repose; that the Macedonians were already much reduced in their numbers; that of those who remained, the greater part were invalids; and that they expected, in consideration of their former services, that he would now lead them back to their native country; an act which, of all others, would most contribute to his own great designs, since it would encourage the youth of Macedonia, and even of all Greece, to follow him in whatever new expedition he pleased to undertake." The king was far from being pleased with this speech of Cœnus, and much less with the disposition of his army, which continued in a deep silence. He therefore dismissed the assembly. But next day he called another, in which he told the soldiers plainly, that he would not be driven from his purpose; that he would proceed in his conquests with such as should follow him voluntarily; and that, as for the rest, he would not detain them, but would leave them at liberty to go home to Macedonia, where they might publish, "that they had left their king in the midst of his enemies." Even this expedient had no success; his army was so thoroughly tired with long marches and desperate battles, that they were determined to advance no further; upon which Alexander retired to his tent, where he refused to see his friends, and evinced the same gloomy temper that reigned amongst his troops.

For three days things remained in this situation. At last the king suddenly appeared; and, as if he had been fully determined to pursue his first design, he gave orders to sacrifice for the good success of his new undertaking. But Aristander the augur reported that the omens were altogether inauspicious; upon which the king said, that since his proceeding farther was neither pleasing to the gods nor grateful to his army, he would return. When this was rumoured amongst the army, they assembled in great numbers about the royal tent, saluting the king with loud acclamations; wishing him success in all his future designs, and giving him at the same time hearty thanks, inasmuch as "he who was invincible had suffered himself to be overcome by their prayers." A stop being thus put to the conquests of Alexander, he determined to make the Hyphasis the boundary of his dominions; and having erected twelve altars of an extraordinary magnitude, he sacrificed upon them, after which he exhibited shows in the Grecian manner; and, having added all the conquered country in these parts to the dominions of Porus, he began to return. Having arrived at the Hydaspes, he made the necessary preparations for sailing down the Indus to the ocean. For this purpose, he ordered vast quantities of timber to be felled in the neighbourhood of the Hydaspes, through which he was to sail into the Indus; and he caused the vessels with which he had passed other rivers to be brought thither, and assembled a vast number of artificers capable of repairing and equipping his fleet, which, when finished, consisted of eighty vessels of three banks of oars, and two thousand lesser ships and transports. Those who were to manage this fleet were collected from among the Phœnicians, Cyprians, Carians, and Egyptians who had followed his army, and were reckoned perfectly well skilled in the nautical art. When all things were ready, the army embarked about break of day; whilst the king, in the mean time, sacrificed to the gods, according to the ceremonies used in his own country, and likewise according to those of the country in which he now was. Then he himself went on board, and causing the signal to be given by sound of trumpet, the fleet set sail. Craterus and Hephæstion had marched some days before with another division of the army; and in three days the fleet reached that part of the river which was opposite to their camps. Here he received information that the Oxydracæ and Malli were raising forces to oppose him, upon which he immediately determined to reduce them; for, during this voyage, he made it a rule to compel the inhabitants on both sides of the river to yield him obedience. But before he arrived amongst the people above mentioned, he himself sustained no small danger; for, coming to the confluence of the Acesines with the Hydaspes, whence both rivers roll together into the Indus, the eddies, whirlpools, and rapid currents, rushing with tremendous noise from the respective channels of those rivers into the great one formed by them both, at once terrified those who navigated his vessels, and actually destroyed many of the long vessels, with all who were on board of them; the king himself being in some danger, and Nearchus the admiral not a little at a loss. As soon as this danger was over, Alexander went on shore; and having ordered his elephants with some troops of horse and archers to be carried across, and put under the command of Craterus, he then divided his army on the left-hand bank into three bodies, the first commanded by himself, the second by Hephæstion, and the third by Ptolemy. Hephæstion had orders to move silently through the heart of the country, five days' march before the king; that if, on Alexander's approach, any of the barbarians should attempt to shelter themselves by retiring into the country, they might fall into the hands of Hephæstion. Ptolemy Lagus was ordered to march three days' journey behind the king, that if any escaped his army, they might fall into Ptolemy's hands; and the fleet had orders to stop at the confluence of this river with the Hydraotes until such time as all these several corps should arrive.

His expedition against the Malli.

Alexander himself, at the head of a body of horse and light-armed foot, marched through a desert country against the Malli, and, scarcely affording any rest to his soldiers, arrived in three days at a city into which the barbarians had put their wives and children, with a good garrison for their defence. The country people, having no notion that Alexander would march through such a desert and barren region, were all unarmed, and in the utmost confusion. Many of them therefore were slain in the fields; the rest fled into the city, and shut the gates. But this only protracted their fate for a short time; for the king, having ordered the city to be invested by his cavalry, took it, as well as the castle, by storm, and put all he found there to the sword. He sent at the same time Perdiccas, with a considerable detachment, to invest another city of the Malli, at a considerable distance; but when he came there he found it abandoned. However, he pursued the inhabitants, who had but lately left it, and killed great numbers of them on the road. After this the king took several other cities, but not without considerable resistance; for the Indians sometimes chose to burn themselves in their houses rather than surrender. At last he marched to their capital city; and finding it abandoned, he proceeded to the river Hydraotes, where he found fifty thousand men encamped on the opposite bank, in order to dispute his passage. He did not hesitate, however, to enter the river with a considerable party of horse; and so much were the Indians terrified at his presence, that their whole army retired before him. In a short time they returned and attacked him, being ashamed to fly before such an inconsiderable number; but in the mean time the rest of the Macedonian forces came up, and the Indians were obliged to retire to a city which lay behind them, and which Alexander invested that very night. The next day he stormed the city with such violence, that the inhabitants were compelled to abandon it, and to retire to the castle, where they prepared for an obstinate defence. The king instantly gave orders for scaling the walls, and the soldiers prepared to execute these orders as fast as they could; but the king being impatient, caught hold of a ladder and mounted it first himself, being followed by Leonatus, Peucestas, and Abreas, the latter a man of great valour, and who on that account had double pay allowed him. The king having gained the top of the battlements, cleared them quickly of the defendants, killing some of them with his sword, and pushing others over the walls; but after this was done, he was in more danger than ever, for the Indians galled him with their arrows from the adjacent towers, though they durst not approach near enough to engage him. His own battalion of targeteers mounting in haste to second him, broke the ladders; which, as soon as Alexander perceived, he threw himself down into the castle, as did also Peucestas, Leonatus, and Abreas. As soon as the king was on the ground, the Indian general rushed forward to attack him; but Alexander instantly despatched him, as well as several others who followed him. Upon this the rest retired, and contented themselves with throwing darts and stones at him at a distance. Abreas was struck in the head with an arrow, and died on the spot; and, shortly after, another pierced through the king's breast-plate into his body. As long as he had spirits, he defended himself valiantly; but, through a vast effusion of blood, losing his senses, he fell upon his shield. Peucestas then covered him with the sacred shield of Pallas on one side, as did Leonatus with his own shield on the other, though they themselves were dreadfully wounded. In the mean time, however, the soldiers on the outside, eager to save their king, supplied their want of ladders by driving large iron pins into the walls. By the help of these many of them ascended, and came to the assistance of Alexander and his companions. The Indians were now slaughtered without mercy; but Alexander continued for some time in a very dangerous way. However, he at last recovered his strength, and showed himself again to his army, which filled them with the greatest joy.

Continues his voyage down the Indus.

The Malli, being now convinced that nothing but submission could save the remainder of them, sent deputies to Alexander, offering the dominion of their country, as did also the Oxydracæ; and the king having settled every thing in these countries agreeable to his mind, proceeded on his voyage down the river Indus. In this voyage he received the submission of some other Indian princes; and perceiving, that at the point of the island Pattala, the river divided itself into two vast branches, he ordered an haven and convenient docks to be made there for his ships; and when he had careened his fleet, he sailed down the right-hand branch towards the ocean. In his passage he sustained great difficulties by reason of the want of pilots, and at the mouth of the river very narrowly missed being cast away; yet all this did not prevent him from pursuing his first design, though it does not appear that he had any other motive thereto than the vain desire of boasting that he had entered the ocean beyond the Indus; for, having consecrated certain bulls to Neptune, and thrown them into the sea, performed certain libations out of golden cups, and thrown the cups also into the sea, he came back again, having only surveyed two little islands, one at the mouth of the Indus, and one a little farther in the ocean. On the king's return to Pattala, he resolved to sail down the other branch of the Indus, that he might see whether it was more safe and commodious for his fleet than that which he had already tried; and for this he had very good reasons. He had resolved to send Nearchus with his fleet by sea, through the Persian Gulf, up the river Tigris, to meet him and his army in Mesopotamia; but as the possibility of this voyage depended on the ceasing of the etesian winds, there was a necessity for laying up the fleet till the season should prove favourable. Alexander, therefore, sailing through this branch of the Indus, sought on the sea-coast for bays and creeks, where his fleet might anchor in safety; he also caused pits to be sunk, which might be filled with fresh water for the use of his people, and took all imaginable precautions for preserving them in ease and safety till the season would allow them to continue their voyage. In this he succeeded to his wish; for he found this branch of the river Indus, at its mouth, spread over the plain country, and forming a kind of lake, in which a fleet might ride with safety. He therefore appointed Leonatus, and a part of his army, to carry on such works as were necessary, causing them to be relieved by fresh troops as often as there was occasion; then having given his last instructions to Nearchus, he departed with the rest of the army, in order to march back to Babylon.

His march through Gedrosia.

Before the king's departure, many of his friends advised him against the route which he intended to take. They told him, that nothing could be more rash or dangerous than this resolution. They informed him, that the country through which he was to travel was a wild uncultivated desert; that Semiramis, when she led her soldiers this way out of India, brought home but twenty of them; and that Cyrus, attempting to do the same, returned with only seven. But all this was so far from deterring Alexander, that it more than ever determined him to pursue no other route. As soon, therefore, as he had put things in order, he marched at the head of a sufficient body of troops to reduce the Oritæ, who had never vouchsafed either to make their submission or to court his friendship. Their territories lay upon the other side of a river called Arabis, which Alexander crossed so speedily, that they had no intelligence of his march; whereupon most of them quitted their country, and fled into the deserts. Their capital he found so well situated, that he resolved to take it out of their hands, and to cause a new and noble city to be founded there, the care of which he committed to Hephæstion. Then he received the deputies of the Oritæ and Gedrosi; and having assured them, that if the people returned to their villages, they should be kindly treated, and having appointed Apollophenes president of the Oritæ, and left a considerable body of troops under Leonatus to secure their obedience, he began his march through Gedrosia. In this march his troops suffered incredible hardships. The road was very uncertain and troublesome, on account of its lying through deep and loose sands, rising in many places into hillocks, which forced the soldiers to climb, at the same time that it sunk under their feet; there were no towns, villages, nor places of refreshment, to be met with; so that, after excessive marches, they were forced to encamp among these dry sands. As to provisions, they hardly met with any during their whole march. The soldiers were therefore obliged to kill their beasts of carriage; and such as were sent to bring some corn from the sea side, were so grievously distressed, that, though it was sealed with the king's signet, they cut open the bags, choosing rather to die a violent death for disobedience than perish by hunger. When the king, however, was informed of this, he freely pardoned the offenders; he was also forced to accept the excuses that were daily made for the loss of mules, horses, &c. which were in truth eaten by the soldiers, and their carriages broken in pieces to avoid further trouble. As for water, their want of it was a great misfortune, and yet their finding it in plenty was sometimes a greater; for, as in the one case they perished with thirst, so in the other they were thrown into dropsies, and rendered incapable of travel. Frequently they met with no water for the whole day together; sometimes they were disappointed of it at night, in which case, if they were able, they marched on; so that it was common with them to travel thirty, forty, fifty, or even sixty miles without encamping. Through these hardships numbers were obliged to fall into the rear; and of these many were left behind, and perished; for indeed scarcely any of them ever joined the army again. Their miseries, however, they sustained with incredible patience, being encouraged by the example of their king, who, on this occasion, suffered greater hardships than the meanest soldier in his army.

Arrival in Caramania.

At last they arrived at the capital of Gedrosia, where they refreshed themselves, and staid some time; after which they marched into Caramania, which being a very plentiful country, made them ample amends for the hardships and fatigues which they had sustained. Here they were joined, first by Craterus with the troops under his command, along with a number of elephants; then came Stasanor, president of the Arians, and Pharismanes, the son of Phrataphernes, the governor of Parthia. They brought with them camels, horses, and other beasts of burden, in vast numbers; having foreseen that the king's march through Gedrosia would be attended with the loss of the greater part, if not all, of the cavalry and beasts belonging to his army. During Alexander's stay in Caramania, he redressed the injuries of his people, who had been grievously oppressed by their governors during his absence. Here also he was joined by his admiral Nearchus, who brought with him an account that all under his command were in perfect safety, and in excellent condition; intelligence with which the king was mightily pleased, and, after having bestowed on him singular marks of his favour, sent him back to the navy. Alexander next set out for Persia, where great disorders had been committed during his absence. These he also redressed, and caused the governor to be crucified; appointing in his room Peucestas, who had saved his life when he fought singly against a whole garrison, as above related. The new governor was no sooner invested with his dignity than he laid aside the Macedonian garb, and put on that of the Medes, being the only one of Alexander's captains who, by complying with the manners of the people he governed, gained their affection.

Whilst Alexander visited the different parts of Persia, he took a view, amongst the rest, of the ruins of Persepolis, where he is said to have expressed great sorrow for the destruction he had formerly occasioned. From Persepolis he marched to Susa, where he gave an extraordinary loose to pleasure, resolving to make himself and his followers some amends for the difficulties which they had hitherto undergone, purposing at the same time so effectually to unite his newly-conquered with his hereditary subjects, that the jealousies and fears which had hitherto tormented both should no longer subsist. With this view he married two wives of the blood royal of Persia; Barsine or Statira, the daughter of Darius, and Parysatis, the daughter of Ochus. Drypetis, another daughter of Darius, he gave to Hephæstion; Amastrine, the daughter of Oxyartes, the brother of Darius, married Craterus; and to the rest of his friends, to the number of eighty, he gave other women of the highest quality. All these marriages were celebrated at once, Alexander himself bestowing fortunes upon them. He likewise directed that an account should be taken of the number of his officers and soldiers who had married Asiatic wives; and though they appeared to be ten thousand, yet he gratified each of them according to his rank. He next resolved to pay the debts of his army, and thereupon issued an edict directing every man to register his name, and the sum he owed; an order with which the soldiers complying slowly, from an apprehension that there was some design against them, Alexander ordered tables heaped with money to be set in all quarters of the camp, and caused every man's debts to be paid on his bare word, without even making any entry of his name, though the whole sum amounted to twenty thousand talents. On such as had distinguished themselves in an extraordinary manner he bestowed crowns of gold. Peucestas received the first, Leonatus the second, Nearchus the third, Onecritus the fourth, Hephæstion the fifth, and the rest of his guards had each of them one. After this he made other dispositions for conciliating, as he supposed, the differences amongst his subjects. He reviewed the thirty thousand youths whom at his departure for India he had ordered to be taught Greek and the Macedonian discipline, expressing high satisfaction at the fine appearance they made, which rendered them worthy of the appellation he bestowed on them, that of *Epigoni*, or successors. He promoted also, without any distinction of nation, all those who had served him faithfully and valiantly in the Indian war. When all these regulations were made, he gave the command of his heavy-armed troops to Hephæstion, and ordered him to march directly to the banks of the Tigris; whilst in the mean time a fleet was equipped for carrying the king and the troops which he retained with him down to the ocean.

His death and character.

Thus ended the exploits of Alexander, the greatest conqueror that ever the world saw, at least with respect to the rapidity of his conquests. In the course of twelve years he had brought under his subjection Egypt, Libya, Asia Minor, Syria, Phœnicia, Palestine, Babylonia, Persia, with part of India and Tartary. Still, however, he meditated greater things. He had now got a great taste for maritime affairs, and is said to have meditated a voyage to the coasts of Arabia and Ethiopia, and thence round the whole continent of Africa to the Straits of Gibraltar. But of this there is no great certainty, though that he intended to subdue the Carthaginians and Italians is more than probable. All these designs, however, were frustrated by his death, which happened at Babylon, in the year 323 before Christ. He is said to have received several warnings of his approaching fate, and to have been advised to avoid that city, which advice he either despised or could not follow. He died of a fever, after eight days' illness, without naming any successor; having only given his ring to Perdiccas, and left the kingdom, as he said, "to the most worthy."

The character of this great prince has been variously represented; but most historians seem to have looked upon him rather as an illustrious madman than one upon whom the epithet of Great could be properly bestowed. From a careful observation of his conduct, however, it must appear that he possessed not only a capacity to plan, but likewise to execute, the greatest enterprises which ever entered into the mind of any of the human race. From whatever cause the notion originated, it is plain that he imagined himself a divine person, and born to subdue the whole world; and extravagant and impracticable as this scheme may appear at present, it cannot at all be looked upon in the same light in the age of Alexander. The Greeks were in his time the most powerful people in the world in respect to their skill in the military art, and the Persians were the most powerful with respect to wealth and numbers. The only other powerful nations in the world were the Carthaginians, Gauls, and Italian nations. From a long series of wars which the Carthaginians carried on in Sicily, it appeared that they were by no means capable of contending with the Greeks, even when they had an immense superiority of numbers; and much less could they have sustained an attack from the whole power of Greece and Asia united. The Gauls and Italians were indeed very brave, and of a martial disposition; but they were barbarous, and could not have resisted armies well disciplined, and under the command of such a skilful leader as Alexander. Even long after this time, it appeared that the Romans themselves could not have resisted the Greeks, since Regulus, after having defeated the Carthaginians, and reduced them to the utmost distress, was totally unable to resist a Carthaginian army commanded by a Greek general, and trained to Greek discipline.

Thus it appears that the scheme of Alexander cannot by any means be accounted that of a madman, or of one who projects great things without judgment, and the means necessary to execute them. If from his actions we consider the end which he most probably had in view could his scheme have been accomplished, we shall find it not only the greatest, but the best, which can possibly be imagined. He did not conquer to destroy, enslave, or oppress, but to civilize and to unite the whole world as one nation. No sooner was a province conquered than he took care of it as if it had been part of his paternal inheritance. He allowed not his soldiers to oppress and plunder the Persians, which they were very much inclined to do; on the contrary, by giving in to the oriental customs himself, he strove to extinguish that inveterate hatred which had so long subsisted between the two nations. In the Scythian countries which he subdued he pursued the same excellent plan. His courage and military skill, in which he never was excelled, were displayed, not with a view to rapine or desultory conquest, but to civilize and induce the barbarous inhabitants to employ themselves in a more proper way of life. Amidst the hardships of a military life, obstinate sieges, bloody battles, and dear-bought victories, he still respected the rights of mankind, and practised the mild virtues of humanity. The conquered nations enjoyed their ancient laws and privileges; the rigours of despotism were softened; arts and industry encouraged; and the proudest Macedonian governors compelled, by the authority and example of Alexander, to observe the rules of justice towards their meanest subjects. To bridle the fierce inhabitants of the Scythian plains, he founded cities and established colonies on the banks of the Iaxartes and Oxus; and those destructive campaigns usually ascribed to his restless activity and blind ambition appeared to the discernment of this extraordinary man, not only essential to the security of the conquests which he had already made, but necessary for the more remote and splendid expeditions which he still purposed to undertake, and which he performed with singular boldness and unexampled success.

He was of a low stature, and somewhat deformed; but the activity and elevation of his mind animated and ennobled his frame. By a life of continual labour, and by an early and habitual practice of the gymnastic exercises, he had hardened his body against the impressions of cold and heat, hunger and thirst, and prepared his robust constitution for bearing such exertions of strength and activity, as have appeared incredible to the undisciplined softness of modern times. In generosity and in prowess he rivalled the greatest heroes of antiquity; and in the race of glory, having finally outstripped all competitors, became ambitious to surpass himself. His superior skill in war gave uninterrupted success to his arms; and his natural humanity, enlightened by the philosophy of Greece, taught him to improve his conquests to the best interests of mankind. In his extensive dominions he built or founded not less than seventy cities; the situation of which, being chosen with consummate wisdom, tended to facilitate communication, to promote commerce, and to diffuse civilization through the greatest nations of the earth. It may be suspected, indeed, that he mistook the extent of human power, when in the course of one reign he undertook to change the face of the world; and that he miscalculated the stubbornness of ignorance and the force of habit, when he attempted to enlighten barbarism, to soften servitude, and to transplant the improvements of Greece into an African and Asiatic soil, where they have never been known to flourish. Yet let not the designs of Alexander be too hastily accused of extravagance. Whoever seriously considers what he actually performed before his thirty-third year, will be cautious of determining what he might have accomplished had he reached the ordinary term of human life. His resources were peculiar to himself; and such views as well as actions became him, as would have become none besides. In the language of a philosophical historian, "he seems to have been given to the world by a peculiar dispensation of Providence, being a man like to none other of the human kind."

Causes of the dissolution of his empire.

With the death of Alexander fell also the glory of the Macedonians, who very soon relapsed into a situation as bad as, or perhaps worse than, that in which they had been before the reign of Philip. This was occasioned principally by his not having distinctly named a successor, and having no child of his own come to the years of discretion to whom the kingdom might seem naturally to belong. The ambition and jealousy of his mother Olympias, of his queen Roxana, and especially of the great commanders of his army, not only prevented a successor from being ever named, but occasioned the death of every person, whether male or female, who was in the least related to Alexander. To have a just notion of the origin of these disturbances, it is necessary in the first place to understand the state of Macedonian affairs at the time of Alexander's death.

When Alexander set out for Asia, he left Antipater in Macedonia, to prevent any disturbances that might arise either there or in Greece. The Greeks, even during the lifetime of Alexander, bore the superiority which he exercised over them with great impatience; and, though nothing could be more gentle than the government of Antipater, yet he was exceedingly hated, because he obliged them to be quiet. One of the last actions of Alexander's life set all Greece in a flame. He had, by an edict, directed all the cities of Greece to recall their exiles; which edict, when it was published at the Olympic games, created much confusion. Many of the cities were afraid, that when the exiles returned they would change the government; most of them doubted their own safety if the edict took effect; and all of them held this peremptory decree to be a total abolition of their liberty. No sooner, therefore, did the news of Alexander's death arrive than they prepared for war.

In Asia the state of things was not much better; not indeed through any inclination of the conquered countries to revolt, but through the dissensions amongst the commanders. In the general council which was called soon after the death of Alexander, it was at last agreed, or rather commanded by the soldiers, after much confusion and altercation, that Aridæus, the brother of Alexander, who had always accompanied the king, and had been wont to sacrifice with him, should assume the sovereignty. This Aridæus was a man of slender parts and judgment, not naturally, but by the wicked practices of Olympias, who had given him poisonous draughts in his infancy, lest he should stand in the way of her son Alexander or any of his family; and for this, or some other reason, Perdiccas, Ptolemy, and most of the cavalry officers, resented his promotion to such a degree that they quitted the assembly, and even the city. However, Meleager, at the head of the phalanx, vigorously supported their first resolution, and threatened loudly to shed the blood of those who affected to rule over their equals, and to assume a kingdom which nowise belonged to them. Aridæus was accordingly arrayed in royal robes, had the arms of Alexander put upon him, and was saluted by the name of Philip, to render him more popular. Thus were two parties formed, at the head of which were Meleager and Perdiccas, both of them pretending vast concern for the public good, yet at bottom desiring nothing more than their own advantage. Perdiccas was a man of high birth, and had a supreme command in the army, was much in favour with Alexander, and one in whom the nobility had placed great confidence. Meleager had become formidable by the phalanx being on his side, and having the nominal king entirely in his power; for Aridæus, or Philip, was obliged to comply with whatever he thought proper, and publicly declared, that whatever he did was by the advice of Meleager; so that he made his minister accountable for his own schemes, and nowise endangered himself. The Macedonians also, besides their regard for the deceased king, soon began to entertain a personal love for Philip on account of his moderation.

Meleag murdere and the empire vided.

It is remarkable, however, that notwithstanding all the favours which Alexander had conferred upon his officers, and the fidelity with which they had served him during his life, only two of them were attached to the interests of his family after his death. These were Antipater, and Eumenes the Cardian, whom he had appointed his secretary. Antipater, as we have already seen, was embroiled with the Greeks, and could not assist the royal family, who were in Asia; and Eumenes had not as yet sufficient interest to form a party in their favour. In a short time, however, Perdiccas prevailed against Meleager, and caused him to be

Meleager murdered, and the empire divided.

murdered; by which means the supreme power for a time fell into his hands. His first step, in consequence of this power, was to distribute the provinces of the empire amongst the commanders, in order at once to prevent competitors, and to satisfy the ambition of the principal leaders of the army. Aridæus, and the son of Roxana, born after the death of his father, were to enjoy the regal authority. Antipater had the government of the European provinces. Craterus received the title of Protector. Perdiccas was made general of the household troops, in the room of Hephæstion. Ptolemy, the son of Lagus, obtained Egypt, Libya, and that part of Arabia which borders upon Egypt. Cleomenes, a man of infamous character, whom Alexander had appointed receiver-general in Egypt, was made Ptolemy's deputy. Leomedon had Syria; Philotas, Cilicia; Python, Media; Eumenes, Cappadocia, Paphlagonia, and all the country bordering on the Euxine Sea, as far as Trapezus; but these were not yet conquered, so that he was a governor without a province. Antigonus received Pamphylia, Lycia, and Phrygia Major; Cassander, Caria; Menander, Lydia; Leonatus, Phrygia on the Hellespont.

Alexander's body neglected, and his will set aside.

In the mean time, not only Alexander's will, but even his remains, were so much neglected, that his body was allowed to lie seven days before any notice was taken of it, or any orders were given for its being embalmed. The only will he left was a short memorandum of six things which he wished to have done. 1. A fleet of one thousand stout galleys was to be built and employed against the Carthaginians and other nations who might oppose the reduction of the sea-coasts of Africa and Spain, with all the adjacent islands as far as Sicily. 2. A large and regular highway was to be constructed along the coast of Africa, as far as Ceuta and Tangier. 3. Six temples of extraordinary magnificence were to be erected, at the expense of one thousand five hundred talents each. 4. Castles, arsenals, havens, and yards for building ships, were to be established in proper places throughout his empire. 5. Several new cities were to be built in Europe and Asia; those in Asia to be inhabited by colonies from Europe, and those in Europe to be filled with Asiatics; that by blending the people and the manners of both, the hereditary antipathy which had hitherto subsisted between the inhabitants of these two continents might, if possible, be eradicated. Lastly, he had projected the building of a pyramid, equal in size and beauty to the largest in Egypt, in honour of his father Philip. But all these designs were, on the pretence of their being expensive, referred to a council of Macedonians, to be held nobody knew when or where.

The daughters of Darius put to death by Roxana.

The government, being now in the hands of Perdiccas and Roxana, soon became cruel and distasteful. Alexander was scarcely dead when the queen sent for Statira and Drypetis, the two daughters of Darius, one of whom had been married to Alexander, and the other to Hephæstion; and as soon as they arrived at Babylon, she caused them both to be murdered, that no son of Alexander by any other woman, or of Hephæstion, might give any trouble to her or her son Alexander. Sisygambis, the mother of Darius, no sooner heard that Alexander the Great was dead, than she laid violent hands on herself, being apprehensive of the calamities which were about to ensue.

Revolt of the Greeks.

War was first declared in Greece against Antipater in the year 321 before Christ; and, through the treachery of the Thessalians, that general was defeated, with the army he had under his own command. Leonatus was therefore sent from Asia, with a very considerable army, to his assistance; but both were overthrown with great loss by the confederates, and Leonatus himself was killed. In a short time, however, Craterus arrived in Greece with a great army, the command of which he resigned to Antipater. The army of the confederates amounted to about twenty-five thousand foot and three thousand horse; but Antipater commanded no fewer than forty thousand foot, three thousand archers, and five thousand horse. In such an unequal contest, therefore, the Greeks were defeated, and forced to sue for peace, which they did not obtain except on condition of their receiving Macedonian garrisons into several of their cities. At Athens also the democratic government was abrogated; and such a dreadful punishment did this seem to the Athenians, that twenty-two thousand of them left their country and retired into Macedonia.

Disturbances in Asia and Thrace.

Whilst these things were doing in Greece, disturbances began also to arise in Asia and in Thrace. The Greek mercenaries, who were dispersed throughout the inland provinces of Asia, despairing of ever being allowed to return home by fair means, determined to attempt it by force. For this purpose they assembled to the number of twenty thousand foot and three thousand horse; but they were all cut off to a man by the Macedonians. In Thrace, Lysimachus was attacked by one Seuthes, a prince of that country, who claimed the dominions of his ancestors, and had raised an army of twenty thousand foot and eight thousand horse. But though the Macedonian commander was forced to engage this army with no more than four thousand foot and two thousand horse, yet he kept the field of battle, and could not be driven out of the country.

Ambition and cruelty of Perdiccas.

Perdiccas, in the mean time, by pretending friendship to the royal family, had gained over Eumenes entirely to his interest; and at last put him in possession of the province of Cappadocia by the defeat of Ariarathes, king of that country, whom he afterwards caused to be crucified. His ambition, however, now began to involve him in difficulties. At the first division of the provinces, Perdiccas, to strengthen his own authority, had proposed to marry Nicæa, the daughter of Antipater; and so well was this proposal relished, that her brethren, Jollas and Archias, conducted her to him, in order to be present at the celebration of the nuptials. But Perdiccas had now other objects in view. He had been solicited by Olympias to marry her daughter Cleopatra, the widow of Alexander king of Epirus, and who then resided at Sardis in Lydia. Eumenes promoted this match to the utmost of his power, because he thought it would be for the interest of the royal family; and his persuasions had such an effect on Perdiccas, that he was sent to Sardis to compliment Cleopatra, and to carry presents to her in name of her new lover. In the absence of Eumenes, however, Alcetas, the brother of Perdiccas, persuaded him to marry Nicæa; but, in order to gratify his ambition, he resolved to divorce her immediately after the marriage, and to marry Cleopatra. By this last alliance he hoped to have a pretence for altering the government of Macedonia; and, as a necessary measure preparative to these, he entered into contrivances for destroying Antigonus. Unfortunately for himself, however, he ruined all his schemes by his own jealousy and precipitate cruelty. Cynane, the daughter of Philip by his second wife, had brought her daughter Adda, who was afterwards named Eurydice, to court, in hopes that King Aridæus might marry her. Against Cynane, Perdiccas, from some political motives, conceived such a grudge, that he caused her to be murdered. This raised a commotion in the army, which frightened Perdiccas to such a degree that he now promoted the match between Aridæus and Eurydice, to prevent which he had murdered the mother of the young princess. But, in the mean time, Antigonus, knowing the designs of Perdiccas against himself, fled with his son Demetrius to Greece, there to take shelter under the protection of Antipater and Craterus, whom he informed of the ambition and cruelty of the regent.

Civil war.

A civil war was now kindled up. Antipater, Craterus, Neoptolemus, and Antigonus, were combined against Perdiccas; and it was the misfortune of the empire in general that Eumenes, the most able general, as well as the most virtuous of all the commanders, was on the side of Perdiccas, because he believed him to be in the interest of Alexander's family. Ptolemy in the mean time remained in quiet possession of Egypt, but without the least intention of owning any person as his superior. However, he also acceded to the league formed against Perdiccas, and thus the only person in the whole empire who consulted the interest of the royal family was Eumenes.

Alexander buried in Egypt.

It was now thought proper to bury the body of Alexander, which had been kept for two years, during all which time preparations had been making for its interment. Aridæus, to whose care it was committed, set out from Babylon for Damascus, in order to carry the king's body to Egypt. This was much against the will of Perdiccas; for it seems there was a superstitious report, that wherever the body of Alexander was laid, that country should flourish most. Perdiccas, therefore, out of regard to his native soil, would have it conveyed to the royal sepulchres in Macedonia; but Aridæus, pleading the late king's express direction, was determined to carry it into Egypt, from thence to be conveyed to the temple of Jupiter Ammon. The funeral was accordingly conducted with all imaginable magnificence. Ptolemy came to meet the body as far as Syria; but, instead of burying it in the temple of Jupiter Ammon, he erected a stately temple for it in the city of Alexandria; and, by the respect which he showed for his dead master, induced to join him many of the Macedonian veterans, who were afterwards of the greatest service to him.

Perdiccas killed, and a new division of the empire.

No sooner was the funeral over, than both the parties above mentioned fell to blows. Perdiccas marched against Ptolemy, but was slain by his own men, who, after the death of their general, submitted to his antagonist; and thus Eumenes was left alone to contend against all the other generals who had served under Alexander. In this contest, however, he would by no means have been overmatched, had his soldiers been attached to him; but as they had been accustomed to serve under those very generals against whom they were now to fight, they were upon all occasions ready to betray and desert Eumenes. However, he defeated and killed Neoptolemus and Craterus; but then found himself obliged to contend with Antipater and Antigonus. Antipater was now appointed protector of the kings, with sovereign power; and Eumenes was about the same time declared a public enemy. A new division of Alexander's empire took place. Egypt, Libya, and the parts adjacent, were given to Ptolemy, because they could not be taken from him. Syria was confirmed to Leomedon. Philoxenus received Cilicia. Mesopotamia and Arbelitus were given to Amphimachus. Babylon was bestowed on Seleucus. Susiana fell to Antigenes, who commanded the Macedonian *Argyraspidæ*, or Silver Shields, because he was the first who opposed Perdiccas. Peucestas held Persia; Tlepolemus had Caramania; Python had Media as far as the Caspian Straits; Stasander had Aria and Drangia; Philip, Parthia; Stasonor, Bactria and Sogdia; Sybirtius, Aracopa; Oxyartes, the father of Roxana, Paropamisus. Another Python had the country between this province and India. Porus and Taxiles retained what Alexander had given them, refusing to part with any portion of their dominions. Cappadocia was assigned to Nicanor. Phrygia Major, Lycaonia, Pamphylia, and Lycia, were given to Antigonus; Caria to Cassander; Lydia to Clytus; and Phrygia the Less to Aridæus. Cassander was appointed general of the horse; whilst the command of the household troops was given to Antigonus, with orders to prosecute the war against Eumenes. Antipater having thus settled every thing as well as he could, returned to Macedonia with the two kings, to the great joy of his countrymen, having left his son Cassander as a check upon Antigonus in Asia.

Total destruction Alexander's family.

Matters now seemed to wear a better aspect than they had yet done; and, if Eumenes had believed that his enemies really consulted the interest of Alexander's family, there is not the least doubt that the war would have been immediately terminated. He saw, however, that the design of Antigonus was only to set up for himself, and consequently he refused to submit. From this time, therefore, the Macedonian empire in Asia ceased to exist; and the Macedonian affairs were now entirely confined to that kingdom itself, and to Greece. Antipater had not been long returned to Macedonia, when he died; and the last action of his life completed the ruin of Alexander's family. With a view to the public good, he had appointed Polysperchon, one of the eldest of Alexander's captains, to be protector and governor of Macedonia. This failed not to disgust his son Cassander, who thought he had a natural right to these offices, and of course kindled up a new civil war in Macedonia. This was indeed highly promoted by his first actions as a governor. He began with attempting to remove all the governors appointed in Greece by Antipater, and to restore democracy wherever it had been abolished. The immediate consequence of this was, that the people refused to obey their magistrates; the governors refused to resign their places, and applied for assistance to Cassander. Polysperchon had also the imprudence to recall Olympias from Epirus, and to allow her a share in the administration, which Antipater, and even Alexander himself, had always refused her. The consequence of all this was, that Cassander invaded Greece, where he prevailed against Polysperchon. Olympias returned to Macedonia, where she cruelly murdered Aridæus and his wife Eurydice. But she was herself put to death by Cassander, who afterwards caused Roxana and her son to be murdered; and Polysperchon being driven into Etolia, first raised to the crown Hercules the son of Alexander by the daughter of Darius, and then, by the instigation of Cassander, murdered him, by which means the line of Alexander the Great became totally extinct.

Various r volutions in the government

Cassander having thus destroyed all the royal family, assumed the regal title, as he had for sixteen years before had all the power. But he enjoyed the title of king of Macedonia only three years, after which he died, about 298 before Christ. By Thessalonica, the daughter of Philip king of Macedonia, he left three sons, Philip, Antipater, and Alexander. Philip succeeded him, but soon afterwards died of a consumption, and a contest immediately began between the two brothers, Antipater and Alexander. Antipater seized the kingdom, and, to secure himself in it, murdered his mother Thessalonica. Alexander invited Pyrrhus king of Epirus, and Demetrius the son of Antigonus, to assist him and revenge the death of his mother. But Pyrrhus being bought off, and a peace concluded between the brothers, Alexander, afraid of having too many protectors, formed a scheme of getting Demetrius assassinated. Instead of this, however, both he and Antipater were put to death; and Demetrius became king of Macedonia, four years after the death of Cassander.

In 287 before Christ, Demetrius was driven out by Pyrrhus, who was again driven out two years after by Lysimachus, who was soon afterwards killed by Seleucus Nicanor; and Seleucus in his turn was murdered by Ptolemy Ceraunus, who became king of Macedonia about 280 before our era. The new king was in a short time cut off, with his whole army, by the Gauls; and Antigonus Gonatus, the son of Demetrius Poliorcetes, became king of Macedonia in 278 before Christ. He proved successful against the Gauls, but was driven out by Pyrrhus king of Epirus, who, however, soon disobliged his subjects to such a degree that Antigonus recovered a great part of his kingdom. But in a little time, Pyrrhus being killed at the siege of Argos in Greece, Antigonus was restored to the whole of Macedonia; but scarcely was he seated on the throne, when he was driven from it by Alexander the son of Pyrrhus. The new invader was in his turn expelled by Demetrius the son of Antigonus, who, though at that time but a boy, had almost made himself master of Epirus. In this enterprise, however, he was disappointed; but by his means Antigonus was restored to his kingdom, which he governed for many years in peace. By a stratagem he made himself master of the city of Corinth, and from that time began to form schemes for the thorough conquest of Greece. The method he took to accomplish this was, to support the petty tyrants of Greece against the free states, which indeed weakened the power of the latter, but involved the whole country in so many calamities, that these transactions redound but little to the reputation either of his arms or of his honour. He died about the year 243, leaving the kingdom to his son Demetrius II.

Neither Demetrius nor his successor Antigonus Doson performed any thing remarkable. In 221 before Christ, the kingdom fell to Philip, the last but one of the Macedonian monarchs. To him Hannibal, after the battle of Cannæ, applied for assistance, which he refused; and the same imprudence which made him refuse this assistance prompted him to embroil himself with the Romans, and at last to conclude a treaty with them, by which he in effect became their subject, being tied up from making peace or war except according to their pleasure. In 179 before Christ he was succeeded by his eldest son Perseus, under whom the war with the Romans was renewed. Even yet the Macedonians were terrible in war; and their phalanx, when properly conducted, seems to have been absolutely invincible by any method of making war at that time known. It consisted of sixteen thousand men, of whom one thousand marched abreast, and thus was sixteen men deep, each of whom carried a kind of long pike denominated *sarissa.* The soldiers stood so close together, that the fifth rank extended the points of their pikes beyond the front of the battle. The hindermost ranks leaned their pikes upon the shoulders of those who went before them, and, locking them fast, pressed briskly against them when they made the charge; so that the first five ranks received the impetus of the whole phalanx, which was the reason why the shock generally proved irresistible. (See the article ARMY, in which the constitution of the phalanx is fully explained.) The Romans had never encountered such a terrible enemy; and in the first battle, which happened 171 before Christ, they were defeated with the loss of two thousand two hundred men, whilst the Macedonians lost no more than sixty. The generals of Perseus now pressed him to storm the enemy's camp; but he being naturally of a cowardly disposition, refused to comply, and thus the best opportunity he ever had was lost. Still, however, the Romans gained little or no advantage over it, until the year 168 before Christ, when Paulus Æmilius, a most experienced commander, was sent to Macedonia. Perseus now put every thing upon the issue of a general engagement; and Æmilius, with all his courage and military experience, would have been defeated, had the Macedonians been commanded by a general of the smallest courage or conduct. The light-armed Macedonians charged with such vigour, that, after the battle, some of their bodies were found within two furlongs of the Roman camp. When the phalanx came to charge, the points of their spears striking into the Roman shields, kept the heavy-armed troops from making any motion; whilst, on the other hand, Perseus's light-armed men did terrible execution. On this occasion, it is said that Æmilius tore his clothes, and gave up all hopes. However, the Roman general, perceiving that as the phalanx gained ground it lost its order in several places, caused his own light-armed troops to charge in those places, whereby the Macedonians were soon thrown into confusion. If Perseus with his horse had, on the first appearance of this, charged the Romans briskly, his infantry would have been enabled to recover themselves; but instead of this, he betook himself to flight, and the infantry at last did the same, but not till twenty thousand of them had lost their lives.

This battle decided the fate of Macedonia, which immediately submitted to the conqueror. The cowardly king took refuge in the island of Samothrace, but was at last obliged to surrender to the Roman consul, by whom he was carried to Rome, led in triumph, and afterwards most barbarously treated. Some pretenders to the throne afterwards appeared; but being unable to defend themselves against the Romans, the country was reduced to a Roman province in the year 148 before Christ.

MACEDONIANS, in *Ecclesiastical History*, the followers of Macedonius, bishop of Constantinople, who, through the influence of the Eunomians, was deposed by the council of Constantinople in 360, and sent into exile. He considered the Holy Ghost as a divine energy diffused throughout the universe, and not as a person distinct from the Father and the Son. The sect of Macedonians was crushed before it had arrived at its full maturity, by the council at Constantinople, in the year 381.

MACER, EMILIUS, an ancient Latin poet, was born at Verona, and flourished under Augustus Cæsar. Eusebius relates that he died a few years after Virgil. Ovid speaks of a poem of his, on the nature and quality of birds, serpents, and herbs, which he says Macer, being then very old, had often read to him. There is extant a poem under Macer's name, upon the nature and power of herbs; but it is evidently spurious. He also wrote a supplement to Homer, as Quintus Calaber did afterwards in Greek.

MACERATA, a delegation of the papal dominions in Italy, in the march of Ancona, and on the Adriatic Sea, extending over 1072 square miles, and containing eight cities, sixteen market-towns, thirty-seven villages, and 197,890 inhabitants. The capital is the city of the same name. It stands on a delightful plain overlooking the Adriatic, and is well built, with broad paved streets. It is the seat of a bishop, and contains eight monasteries, five nunneries, and, besides the cathedral, thirteen churches, with 15,500 inhabitants. There is a university, founded in 1290 and re-established in 1540, a Jesuits' college, and a gymnasium for nobles. Long. 13. 21. E. Lat. 45. 18. 36. N.

MACERATION is an infusion or soaking of ingredients in water, or any other fluid, in order either to soften them or extract their virtues.

MACHAON, a celebrated physician amongst the ancients, was the son of Æsculapius and brother to Podalirius. He went to the Trojan war with the inhabitants of Trica, Ithome, and Œchalia. According to some, he was king of Messenia. He was physician to the Greeks, and healed the wounds which they received during this long war. Some suppose that he was killed before Troy, by Eurypylus, the son of Telephus. He received divine honours after his death, and had a temple in Messenia.

MACHÆRUS, in *Ancient Geography*, a citadel on the other side of Jordan, near the mountains of Moab, not far from and to the north of the Lake Asphaltites. It was the south boundary of the Peræa, and situated on a mountain encompassed round with deep and broad valleys, being built by Alexander king of the Jews. It was destroyed by Gabinius in the war with Aristobulus, and rebuilt by Herod, with a town of the same name around it. Here John the Baptist was beheaded.

MACHAULT, a town of the department of the North, and arrondissement of Bouziers, in France. It is an ancient place, with 1200 inhabitants.

MACHECOUL, a city of France, in the department of the Lower Loire, and arrondissement of Mentz. It is situated on the river Tenu, and contains 600 houses, with 3650 inhabitants. Long. 1. 57. W. Lat. 47. 2. N.

MACHERLA, a town of Hindustan, in the province of the Carnatic, district of Palnaud, 106 miles south from Hyderabad. Long. 78. 54. E. Lat. 16. 8. N.

MACHIAVELLI, Nicolo, for many years secretary of the republic of Florence, and justly celebrated for his political, historical, and other writings, was born at Florence on the 3d of May 1469, being descended from a family which traced its origin up to the ancient marquises of Tuscany, particularly to the Marquis Hugo, who lived about the middle of the ninth century. The Machiavellis were signors or lords of Monte-Spertoli; but preferring the right of citizenship in Florence to the useless conservation of privileges which were daily becoming more and more obnoxious to the rising commonwealth, they prudently submitted to its laws in order to accept employment in the highest offices of the magistracy. This family was one of those attached to the Guelfic party which abandoned Florence in the year 1260, after the defeat at Monte-Aperti. But their secession was merely temporary. Having returned to their native country, they regained their influence, and occupied some of the first offices of the state; no less than thirteen of their number having held the situation of gonfaloniere of justice, and fifty-three that of prior, dignities which were then considered as the most important in the republic. The father of Machiavelli was a jurisconsult, and lived in a state but little removed from poverty. His mother, who appears to have been a woman of talent, loved poetry, and composed verses with facility. It is believed that, about the year 1494, he was placed under the tuition of the learned Marcello di Virgilio, professor of Greek and Latin literature, and the translator of Dioscorides. How long he remained under the care of this master, or what advantages he derived from his instructions, has not been ascertained. But, five years later, when he had scarcely completed his twenty-ninth year, he was preferred, amongst four competitors, to the employment of chancellor of the second chancery of the Signory; a few months afterwards, he was appointed, by the Signory and the colleges, secretary to the ten magistrates of liberty and peace, which constituted the general government of the republic; and with this employment he continued invested for about fourteen years and a half. His ordinary occupations, when he resided at Florence, comprehended the political correspondence, both internal and external, the recording of the deliberations of the council of magistrates, and the redaction of treaties with foreign states.

But the Florentine government, justly appreciating the talents of Machiavelli, were not long in extending his functions; and he was in consequence successively intrusted with no less than twenty-three foreign legations, besides frequent commissions to the cities dependent on the republic. The first mission on which he was despatched was to France, where he arrived in 1500, soon after the raising of the siege of Pisa. Louis XII. had furnished to the Florentines troops and artillery to form the siege of that place; and the republic had sent to the camp two commissioners, besides its secretary Machiavelli, who carried on the correspondence. The Pisans, however, negociated with the king, and at the same time gained over the principal officers in the besieging army. The French troops were to be paid by the Florentines, but some delay having occurred in forwarding their pay, they availed themselves of this as a pretext, and having disbanded, the siege was in consequence raised. The French king reproached the Florentines for the disgrace which had thus been brought on his arms; and it was to appease him, and if possible to obtain fresh succours, that they sent to France Machiavelli, and Francisco della Casa, who had been one of the commissioners in the camp before Pisa. During this negociation, which lasted five months, the deputies followed the court to Saint-Pierre-le-Moutier, Montargis, Melun, Blois, Nantes, and Tours. They had several audiences of the king, and his minister Cardinal d'Amboise; but these led to no satisfactory result. The envoys were continually met with the same reproaches, and the court was only appeased by the reimbursement of the sums which the king had advanced to the troops.[1]

In the year 1502 Machiavelli was sent to the Duke di Valentino (Cesare Borgia) at Imola, and next to Rome. He also went a second time to France, and afterwards to Siena, to Piombino, and to Perugia. In 1507 he proceeded by Geneva to Constance, and from thence to Bolzano, at that time the residence of the Emperor Maximilian, with whom he treated of important affairs. The relation of this mission is printed amongst his complete works, under the title of *Rapporto di cose della Magna, fatto questo dì* 17 *giugno* 1508. In 1510 he re-appeared in France, and, after passing about two months at Blois, witnessed the opening of the national council at Tours. A fourth mission to the court of Louis XII. is commonly referred to the following year, 1511; but it appears uncertain whether it was actually undertaken. It may with truth be said, however, that if Machiavelli failed to secure the complete independence of his country, this proceeded from no fault of his own; inasmuch as the accomplishment of such an object would have required more confidence on the part of his fellow-citizens, greater harmony between the different opinions which then divided the city, and times less turbulent and unpropitious. But the glory cannot be denied him of having attempted this noble enterprise, and devoted to its accomplishment all his genius, and all the influence which he was permitted to exercise in the conduct of public affairs.

This is fully established by his political correspondence, which, besides, is in the highest degree valuable and interesting. His despatches, indeed, form one of the most amusing and instructive collections extant. In them we meet with none of that mystical and verbose jargon which is so common in modern state-papers. The narratives are clearly and agreeably written, and the remarks on men and things are equally shrewd and judicious. We are introduced into the presence of men who, during twenty years, swayed the destinies of Europe. Their wit and their folly, their gloom and their gaiety, are alike exposed to us; we are admitted to overhear their familiar talk, to see the masters of the world in undress, and to observe the manifestations of their real characters. It is interesting and curious to recognise, in circumstances which commonly elude the notice of historians, the feeble violence and the shallow cunning of Louis XII.; the bustling insignificance of Maximilian, a prince afflicted with an impotent desire of renown, rash yet timid, obstinate yet fickle, always in a hurry, yet always too late; the fierce and haughty energy which gave dignity to the eccentricities of the magnificent Julius; and the soft, smooth, calm, graceful manners which masked the insatiable ambition and deadly hatred of Cesare Borgia. The meeting of the Florentine secretary and the Duke di Valentino, of the greatest speculative and the ablest practical statesman of the age, is a memorable occurrence in the history of both. Upon two important occasions Machiavelli was admitted to the society of Borgia; once, at the moment when his splendid villany had achieved its most signal triumph, when he caught in one snare, and crushed at one blow, all his most formidable rivals;[2] and again when, exhausted by disease, and overwhelmed by misfortunes, he was the prisoner of the deadliest enemy of his house. These interviews are fully described in the correspondence. Several writers have supposed that there existed a close and intimate connexion between these remarkable men, and the secretary-envoy has even been accused of prompting the crimes of this artful and merciless tyrant; but, from the official documents, it is evident that their intercourse, though ostensibly of an amicable, was in reality of a hostile description. "It cannot be doubted, however," says an able writer, "that the imagination of Machiavelli was strongly impressed, and his speculations on government coloured, by the observations which he made on the singular character, and equally singular fortunes, of a man who, under such disadvantages, had achieved such exploits; who, when sensuality, varied through innumerable forms, could no longer stimulate his sated mind, found a more powerful and durable excitement in the intense thirst of empire and revenge; who emerged from the sloth and luxury of the Roman purple the first prince and general of the age; who, after acquiring sovereignty by destroying his enemies, acquired popularity by destroying his tools; who had begun to employ for the most salutary ends the power which he had attained by the most atrocious means; who tolerated within the sphere of his iron despotism no plunderer or oppressor but himself; and who fell at last, amidst the mingled curses and regrets of a people, of whom his genius had been the wonder, and might have been the salvation."[1] Some of the crimes of Borgia, which appear to us the most revolting, would not have been viewed with equal horror by an Italian of the fifteenth century; and, besides, patriotic feeling might induce Machiavelli to regard with indulgence and regret the memory of the only leader capable of defending the independence of Italy against the confederate spoilers who were then plotting the dismemberment of that divided and unhappy country.

---

[1] Ginguené, *Histoire Littéraire d'Italie*, tom. viii.

[2] See in *Opere di Machiavelli* (vol. ii. Hague, 1726), *Descrittione del modo tenuto dal Duca Valentino nello amazzare Vitellozzo-Vitelli, Oliverotto da Fermo, il Signor Pagolo, et il Duca di Gravina Orsini.*

But whilst Machiavelli deeply regretted the misfortunes of his country, he clearly discerned the cause and the remedy of these. It was the military system of the Italian people which had extinguished their valour and discipline, destroyed their independence, and rendered their wealth an easy prey to every foreign plunderer. Machiavelli projected a scheme for abolishing the practice of employing mercenary troops, and organizing a national militia; and the exertions which he made to accomplish this grand object are alike honourable to his understanding and his patriotism. He studied with assiduity the art of war, and made himself master of all its details.[2] When levies were decreed, he flew from place to place to superintend the execution of his design, and availed himself of every circumstance which could contribute to its success. For a time the scheme promised well, and the new troops acquitted themselves respectably. But the fury of parties continued to increase, and the tide of misfortune came on before the barriers which should have withstood it were prepared. The emperor and the pope wished to re-establish the Medici, and the moment was favourable for such an enterprise. Florence was then governed by the gonfaloniere Soderini, a man equally presumptuous and feeble, who obstinately adhered to France, without discerning that that power was not in a condition to afford him any aid. It was in reference to this inconsiderate policy that Machiavelli observed, "The good fortune of France has made us lose half the state; her bad fortune will cause the loss of our liberty."[3] The prediction was not long in being verified. As soon as the French armies had lost their superiority in Italy, the storm burst upon Florence. In 1512, the pope and the emperor combined against their common enemy, and, contrary to the faith of treaties, imposed a contribution of a hundred thousand florins. Machiavelli flew through the territory of the republic, to examine the state of the fortresses, and organize a vigorous resistance; but all his efforts were unavailing, and divided Florence soon opened its gates to the Medici, who re-conquered at once their property and their ancient authority.

This revolution, which caused the ruin of the gonfaloniere, proved also the signal for the fall of the secretary. The new Signory immediately attacked him in two decrees, dated the 8th and 10th of November 1514. By the one he was deprived, "absolutely despoiled," of his offices of chancellor and secretary to the ten magistrates of liberty and peace; by the other he was exiled for a year to a part of the Florentine territory, which he was forbidden to quit under the penalty of incurring the displeasure of the Signory. A third decree, dated the 17th of the same month, prohibited him from entering the palace of the high and magnificent signors. On this subject Ginguené has omitted some facts. "Machiavelli," says he, "after fourteen years of service useful to his country, was first deprived of his employment, and then confined for a year to the territory of the republic, with a prohibition not to set foot in the palace of the Signory. Nor was this the term, it was in fact only the commencement of his misfortunes." And he adds in a note, that the fate of the secretary was decided by three decrees of the 8th, 10th, and 17th of November. There appears to be some confusion in this statement. The decree of the 17th was evidently a mitigation of that of the 10th. The latter banished him for a year, and intimated to him that he was not to leave the territory of the republic; that is, it ordained him to quit Florence in order to live in the Florentine dominions, exclusive of the city properly so called. The third decree, dated the 17th, only prohibited him from entering the palace of the Signory, without ordaining him to leave the city; but another decree of the same date was published, in which he was permitted to enter the palace during the whole of the day of the 17th; and the same liberty was granted him on the 4th of December 1512, and on the 21st of March and 9th of July 1513. Ginguené has refuted some of the statements published respecting the treatment Machiavelli is alleged to have experienced after the return of the Medici; but it is not the less true, as appears by the subsequent modifications of the original decree, to the extent already stated, that the removal of the secretary was considered as an affair of some difficulty, and one the accomplishment of which required management and address. But when this object had been effected, he found himself exposed to the greatest dangers. Accused of being concerned in the conspiracy formed by Capponi and Boscoli against Cardinal de' Medici, afterwards Leo X., he was thrown into prison, and put to the torture, which he endured with unflinching resolution. "I have been near losing my life," said he, "which God and my own innocence have saved; I have supported all evils, including imprisonment and others." On the accession of Leo X. he was included in an amnesty, and owed his deliverance to the generosity of that liberal and accomplished pontiff.

These terrible trials, which extraordinary courage can alone withstand, attest the energy and the force of character which belonged to the fallen statesman. Instead of yielding to despondency, he sought for an alleviation of his lot in study and in literature; and it is to his misfortunes that we are indebted for the best known of his works, the

[3] Speaking, on one occasion, of the alliance with France, he observed, *che la buona fortuna di essa aveva fatto perder la metà dello stato, la cattiva avrebbe fatto perdere la libertà.*

Prince, the dialogue on the *Art of War*, his *Histories*, and *Comedies*, which he composed during his retirement at San-Casciano, and which, with the collection of his political letters, deserve to be classed amongst the most remarkable monuments of modern literature. From his retreat, however, he wrote to the friends whom he had still preserved, signifying his desire to be again employed in the conduct of affairs; and his wishes in this respect were to a certain extent gratified. After the death of Lorenzo de' Medici, Leo X. who possessed great influence in the government of Florence, recalled Machiavelli, and requested him to point out the means of reforming the administration. In 1521, there was confided to him a mission to the minor brothers at Carpi. He was next ordered to fortify anew the city, and to treat of some affairs with Francisco Guicciardini, then governor of Romagna. Finally, he was employed in the army of the league against Charles V. This commission was the last remarkable occupation of his life. He returned to Florence in one of the last days of May 1527, and having, not long afterwards, suffered much inconvenience from pains in the stomach, he took a medicine in which he had great faith for relieving this disorder; but being soon attacked by violent spasms in the bowels, he expired on the 22d of June, at the age of fifty-eight, after having received all the sacraments of the church. The following letter from his son Pietro to Francisco Nelli, professor at Pisa, annihilates all the fables which have been circulated respecting his death:—"I cannot tell you without tears, that, on the 22d of this month, our father Nicolo died of pains in the bowels, caused by a medicine which he had taken two days before. He was made to confess his sins by the friar Matteo, who kept him company till his death. Our father has left us in great poverty, as you know." Machiavelli was in his person of the ordinary size, his complexion was of an olive hue, and his physiognomy animated and expressive; in conversation he was at once simple and lively, and his repartee was prompt and piquant. Conversing one day with Clodio Tolomeo, the latter said to him, "At Florence the men have less science, and are less learned, than at Siena, always excepting yourself;" to which Machiavelli replied, "At Siena the men are greater fools than at Florence, not even excepting you." Some one having remarked to him that he had taught princes to be tyrants, he replied, "If I have taught princes to be tyrants, I have also taught the people to destroy tyrants." He was interred in the church of Santa-Croce, in the burying-place of his family; but for more than two centuries his bones lay undistinguished, and it was reserved for an English nobleman, Earl Cowper, to pay the last honours to the greatest statesman of Florence, by erecting a monument to his memory.[1]

Several writings of the Florentine secretary are regarded as estimable productions of a superior mind; others are considered as pernicious, and containing abominable doctrines. Amongst the latter are the apology for the conduct of the Duke di Valentino, when he caused Vitellozzo-Vitelli and others to be massacred at Sinigaglia (*Il modo tenuto dal Duca Valentino*, &c.); the treatise of the Prince (*Il Principe*); and some detached opinions contained in the Discourses on Titus Livius (*Discorsi sopra la prima deca di T. Livio*), which opinions, forming part of a writing posterior to the composition of the *Principe*, will, as far as possible, be explained in the more detailed exposition which we shall endeavour to give of the object and intentions of the author when he composed that celebrated treatise.

At the head of the works generally admitted to have established beyond all dispute the reputation of Machiavelli as a profound thinker, and a politician of inexhaustible genius, may be placed those letters or despatches, published under the title of *Legazioni*, of which we have already spoken incidentally. Ginguené has observed, in reference to these letters, that one would not willingly read the collection, which he considers somewhat diffuse, but that, in regard to the character and life of the secretary, and the history of his own time, it may be consulted with advantage. In this opinion, however, we cannot by any means concur. The collection is suited to the taste of the age, and the country to which it belongs; nor has this taste materially changed; for even the Italian diplomatists of the present day frequently indulge in similar details, introducing such arguments as they think fitted to support their observations, and to create a favourable impression of their zeal and industry. That the *Legazioni* sometimes descended into minutiæ which may be considered as trifling or irrelevant, we readily admit; but even these particulars are by no means devoid of interest; and as to the entire collection, a reader of intelligence cannot peruse it without being at once amused and instructed by it.

The seven books on the Art of War (*Dell' Arte della Guerra*) show that Machiavelli was profoundly conversant with the principles of military science. An Italian writer, adverting to this circumstance, observes, that such knowledge is not only wonderful in a man devoted to civil occupations, but might even be considered as extraordinary in an old general. According to the author of the preface to the edition of 1813, Machiavelli had acquired this insight into military science in consequence of profound meditations on the works of the ancient Romans, who may be regarded as the first masters of the art of war; and, in fact, the combinations of the secretary have constant reference to those of Vegetius. His principal object was to establish the superiority of infantry, at a time when this branch of the service had fallen into general discredit; and his theories fortunately attracted so much regard, that to him may, in a great measure, be attributed the return of sound tactics, and the perfection to which the art of war subsequently attained. Algarotti, in his fourth discourse on the studies of Palladio, gives us to understand that that celebrated architect learned the military art in the writings of the Florentine secretary; Frederick II. has described, in agreeable verses, some of his military precepts; and there is a French work, entitled *Instructions sur le fait de la Guerre, extraites des livres de Polybe, Frontin, Vegèce, Machiavelli, et plusieurs autres bons auteurs*, Paris, 1563. Of the tactics of Machiavelli it is not necessary to express here any opinion. But the treatise is able and interesting; as a commentary on the history of the times it is invaluable; whilst the ingenuity, grace, and perspicuity of the style, and the eloquence and animation of particular passages, must give pleasure even to readers who take no interest in the subject which the author treats with so much skill and ability.[2]

The *Discorsi*, written about the year 1516, the epoch of

[1] This monument, which is the work of Spinazzi, bears the inscription, *Tanto nomini nullum par elogium, Nicolaus Machiavelli obiit* A. P. V. MDXXVII.

[2] The treatise on the Art of War is in the form of a dialogue, and the opinions of the writer are put into the mouth of Fabrizio Colonna, a nobleman of the ecclesiastical state, and an officer of distinguished merit in the service of the king of Spain. After some preliminary conversation, Fabrizio expresses his regret that those who in later times affected the manners of the old Romans, should select for imitation their most trifling pursuits. This leads to a discourse on the decline of military discipline, and the best means of restoring it. The institution of the Florentine militia, to which we have already alluded, is very ably defended; and several improvements are suggested in the details.

The Swiss and the Spaniards were at this time regarded as the best soldiers in Europe. The Swiss battalion consisted of pikemen in deep formation, and bore a close resemblance to the Grecian phalanx. The Spaniards, like the soldiers of Rome, were armed his disgrace, prove that the principles of the author were uniform and constant, and that his views and observations had always a character of justness, depth, and gravity. The Roman republic, in its constitution and its establishments, contained the germs of its greatness; and the inroads committed upon these were the causes of its decline. Machiavelli followed this fatal progress beyond the history of Livy; he discerned and meditated on it in the *Annals* and in the *History* of Tacitus. He there found not only facts, but results; a manner and a style, which he adopted as models. Tacitus became his master in the art of observing, and also, in one sense, in the art of writing; what he had acquired in the study of the former of these two great historians he carried to the school of the latter; and it may be said that he learned from Tacitus to read and explain Livy. After having laid the foundations of his work on the history of Rome, Machiavelli employed himself in following Livy step by step in the perusal of that history; stopping short at every thing which suggested a reflection, or indicated the application of a principle. The text of the historian disappears, or is but rarely cited; actions, institutions, and laws, are alone discussed. The objects of comparison, ancient as well as modern, spring up, so to speak, every instant; luminous results are thence deduced; and an inexhaustible variety of facts continually supports the evidence of the reasonings and the solidity of the maxims. Throughout we discover a mind habituated to profound meditations, and a firmness of soul tried and exercised by the storms of liberty. See, for example, to what he reduces, in his fourth chapter, all the noise made by the quarrels between the senate and the Roman people, which he does not hesitate to regard as the primary cause of the liberty of Rome. Observe also, in his seventh chapter, the strong reasons upon which he grounds the utility, or rather the necessity, of public accusations; and with what justness of discrimination he distinguishes, in his eighth chapter, the effect of public accusations, preferred on public grounds, from those of adulation and calumny. In a word, he reasons inductively from history as he finds it, and deduces his conclusions, not from any appeal to general or speculative principles, but from the facts as these are detailed in the pages of the historian. If he errs, it is only because his experience, acquired in a peculiar state of society, does not always enable him to calculate the effect of institutions differing from those of which he had observed the operation; but in regard to all that comes within the sphere of his own observation or experience, his sagacity is seldom at fault, and he may justly be considered as the founder of that science which has been somewhat vaguely denominated the philosophy of history.

The books *Delle Historie Fiorentine*, a work in which he begins by describing the events which brought about the destruction of the Roman empire, are altogether an admirable composition, and entitle Machiavelli to a separate place amongst historians, seeing that the ancients have not left any model on which he could form a particular style. The first book displays the science and penetration of the writer; and it may be supposed that Bossuet was filled with admiration of his free, bold, rapid, and independent manner, when he sketched the plan of his Discourse on Universal History. The narrative in the seven other books proceeds with the same vivacity; nor can the most careless reader fail to receive from it a vivid and faithful impression of the national character and manners of the Florentines. This work was undoubtedly the last of the author. He is believed to have completed it in 1525; and it was his intention, we are told, to continue it, which is rendered probable by the fragments collected after his decease. The general character of Machiavelli's style, particularly in the History and in the Life of Castruccio, is elegance and simplicity. He is always full of grace without artifice, and of elegance without insipidity; he is clear without being verbose, and concise without obscurity or pretension to the mysterious; and such is the transparency of the medium through which his ideas are conveyed, that the actual depth of the current of thought is not at first discernible.

Although the real merit of the Florentine secretary consists in his profound knowledge of the science of government, in which he has not been surpassed either amongst the ancients or the moderns, yet he is also entitled to a distinguished place amongst comic authors. His *Mandragola*, which, according to Voltaire, surpasses all the comedies of Aristophanes, is superior to the best of Goldoni, and inferior only to the best of Molière; in fact, it is the work of a man who, if he had devoted himself to the drama, would probably have attained the very highest excellence, and produced a permanent and salutary impression upon the national taste. By the correct and vigorous delineation of human character, it produces interest without a skilful or pleasing plot, and laughter without the least ambition or affectation. Machiavelli had an exquisite sense of the ridiculous, and his dramatic humour, which has often been compared to that of Molière, and certainly resembles it in comic force, if not in benevolent gaiety and chastened morality, seldom fails to prove effective. The *Clizia* is an imitation of the *Casina* of Plautus, which is itself an imitation of the lost Κληρουμενοι of Diphilus. Machiavelli has executed his task with judgment and taste, accommodating the plot to a different state of society, and dexterously connecting with it the history of his own times. Besides these, the *Maschere*, the *Andria*, and two other comedies without titles, the one in prose and the other in verse, appear amongst the works of Machiavelli. The charming little novel of *Belphegor* is also pleasantly conceived and wittily told; but the extravagance of the satire in some measure injures its effect. Machiavelli was unhappily married; and his wish to avenge his own cause as well as

---

with the sword and the shield. But the victories gained by Flaminius and Æmilius over the Macedonian kings seemed to prove that the weapons used by the legions were superior to those of the phalanx. And the same experiment had been recently tried with the same result at the battle of Ravenna, "one of those tremendous days into which human folly and wickedness compress the whole devastation of a famine or a plague." In that dreadful conflict, the infantry of Aragon, deserted by their allies, hewed a passage through the thickest of the imperial pikes, and effected an unbroken retreat, in the face of the gensdarmerie of De Foix, and the artillery of Este. Machiavelli, struck with these facts, proposes to combine both systems; to arm the foremost lines with the pike, for the purpose of repulsing cavalry, and those in the rear with the sword, as being a handy weapon, adapted to almost every exigency. He expresses the highest admiration of the military science of the ancient Romans, and the greatest contempt for the maxims in vogue amongst the Italian commanders of the preceding generation; he prefers infantry to cavalry, and fortified camps to fortified towns; he recommends the substitution of rapid movements and decisive engagements for the languid and dilatory operations of his countrymen; and he attaches but little importance to the invention of gunpowder, which, he seems to think, ought scarcely to produce any change in the mode of arming or disposing troops. The artillery of those days was ill constructed, ill served, and consequently of little use in the field of battle; this arm was then in a rude, inefficient state, and hence might in a great measure be disregarded in a general system of tactics; but if Machiavelli could have foreseen the improvements which were destined to take place, particularly in point of mobility, he would have been convinced that a change both in the mode of arming and disposing troops would in consequence become necessary, and that the deep formations of ancient times durst no longer be opposed to the ravages of shot, shells, grape, canister, and the other destructive missiles discharged by modern artillery.

that of his brethren in misfortune carried him beyond even the license of fiction.[1]

Machiavelli was also a poet, though, in this capacity, he is not perhaps entitled to a very high place. The *Decennali* are merely abstracts in verse of the history of his own times. The style and versification are sedulously modelled on those of Dante; but the manner of Dante, like that of every other great original poet, was suited only to his own genius and his own subject, and did not therefore admit of being copied or imitated. The *Assino d'Oro* and the *Capitoli* are also formed on the same model, and are in every respect superior. The Golden Ass indeed has nothing but the name in common with the romance of Apuleius, which, in spite of its irregular plan and vicious style, is one of the most fascinating books in the Latin language, combining the various merits of Le Sage and Radcliffe, Bunyan and Crébillon. The poem of Machiavelli, which is evidently unfinished, is copied from the earlier cantos of the Inferno; whole lines are transferred without acknowledgment, and all without producing their wonted effect; the flowers of language which have bloomed upon one soil, wither when transplanted to another. Yet the *Assino d'Oro* is not altogether destitute of merit; the allegory displays considerable ingenuity, and there is some vivid colouring in the descriptions.

But, of all the works of Machiavelli, that which has excited the greatest attention is the celebrated treatise entitled *Il Principe*. This production, in which the ferocious Borgia is, according to the supposition of several writers, presented as a model to sovereigns who wish to govern absolutely, has acquired a deplorable reputation in Europe, and made the author himself be regarded by many as an incarnation of the evil principle.[2] The first edition, known as that of Antonio Blado d'Asola, appeared at Rome on the 4th of January 1532, accompanied with a privilege of Pope Clement VII. and dedicated to Philip Strozzi, the friend of the author. Bayle speaks of an edition of 1515, which no one has seen, there being, in all probability, a misprint in the date. The Giunta reprinted the *Prince* the same year, 1532, and again in 1540. The sons of Aldus also published it at Venice in 1540; and Gabriel Giolito gave an edition of it in 1550. It was successively translated into German, Montbéliard, 1626; twice into Latin; then into French by Amelot de la Houssaye (Amsterdam, 1683, and Hague, 1743), and, lastly, by Giraudet in 1799, along with the complete works of the author.

We know not of any work which has excited so much discussion and controversy as this, or which has been so often and so vehemently assailed. The intentions of the author have been variously interpreted. Some, thinking they saw in it a complete system of irreligion, impiety, and tyranny, have cried out "Wolf, wolf;"[3] whilst others have demanded that, according to the rules of just criticism, the work should be judged of as a whole, not by detached or disfigured fragments, and that, above all, the disapprobation with which the author always accompanies the exposition of the perverse principles he has developed, should not be dissembled or concealed. Voltaire, writing to the prince-royal of Prussia (20th May 1738), observes: "The first thing I am obliged to advert to is the manner in which you think of Machiavel. Why should you be moved with the virtuous displeasure which you express against me because I have praised the style of a bad man? It is for the Borgias, father and son, and all those petty princes who require crimes to effect their elevation, to study this infernal policy. It belongs to such a prince as you to detest it. This art, which may be classed with that of the Locustes and the Brinvilliers, may give to some tyrants a temporary sway, just as poison may procure an inheritance; but most assuredly it has never made men either great or happy. What, then, can any one accomplish by pursuing this frightful policy? Nothing but misery to others, and also to himself. These are the truths which should form the catechism of your exalted soul." On the 26th of June 1739, the prince replies to this flattering homage in the true French style, by informing his correspondent that what he meditates against Machiavelism is properly a continuation of the Henriade. "It is out of the noble sentiments of Henri IV." says he, "that I am forging the thunderbolt which will crush Cesare Borgia." On the 27th of December, Voltaire renders homage for homage. "We shall at length," says he, "have a book worthy of a prince; and I doubt not that an edition of Machiavel, with this counter-poison at the end of each chapter, will be one of the most precious monuments of literature." "The *Anti-Machiavel*," he adds, "ought to become the catechism of kings, and of their ministers." The book which, in this commerce of flattery, Voltaire denominates *Anti-Machiavel*, is the *Examen du Prince de Machiavel*, by the prince-royal, afterwards king of Prussia, who, in his preface, declares that "he always looked upon the *Prince* as one of the most dangerous works that ever was published," though he afterwards lived long enough to find some of its maxims more convenient and agreeable than he had at first anticipated.

It would be equally endless and impertinent to relate the host of criticisms and apologies, of accusations and defences, of which Machiavelli has been the object, in almost all the languages of Europe. But we shall cite the authority of a judge whom it will not be easy to refute; we mean that of the Florentine secretary himself. Before finishing his treatise of the *Prince*, he wrote to one of his friends, Francisco Vettori, a letter, which discloses without any reserve his real position and his motives, and thus puts an end to all speculation upon the subject. This letter, found in the Barberini library at Rome, was published for the first time by Angelo Ridolfi, in a work entitled *Pensieri intorno allo scopo di Nicolo Machiavello nel libro Il Principe*, Milan, 1810; and Ginguené has also cited it in his *Histoire Littéraire d'Italie*, though, for some reason, he has divided it into two parts, giving the one half in the text, and the other half in a note. The first part contains details which may perhaps be considered as ignoble, but which nevertheless make known the peculiar cast of character, as well as the patience, of the author; the second shows him in all the dignity of his talent. We shall only cite the portion which has immediate reference to the subject before us.

"On the approach of evening," says he, continuing the description of his habits and mode of life, "I retire to my dwelling, and enter my cabinet; at the door I divest myself of my peasant's garb, bedaubed with mud and dirt, put on proper attire, and thus decently dressed I enter the ancient courts of men of old. Being well received by them, I fill myself with that nourishment which alone agrees with me, and for which I was born; nor do I hesitate to converse with them, and to inquire the motives of their actions; whilst they, on the other hand, being full of humanity, reply to my inquiries. For four hours I experience no weariness; I forget all sorrow; I have no dread of poverty, and death no longer alarms me; I transport myself entirely to them; and, as Dante says that *there will never be science unless we retain what we have learned*, I have noted down the substance of my conversation with them, and composed a work, *De Principatibus*, in which I enter as deeply as I can into this subject, with a view to fathom it. I examine what a principality is; how many kinds there are of them; how they are acquired, how maintained, how lost; and if ever any trifle (*ghiribizzo*) of mine gave you pleasure, this should not displease you. It should also be acceptable to a prince, more especially to a new one; wherefore I address it to the magnificent Julius.[1] Philip Casavecchia has seen my treatise, and can inform you in detail of the subject itself, and the arguments I have had with him; and as to myself, I am now occupied in extending and correcting it. You wish that I should abandon my actual mode of life, and go to enjoy yours; I will do so gladly; but I am prevented at present by some affairs which will be settled in about six weeks. The only thing which makes me hesitate is, that, near these Soderini, I shall be obliged, on my arrival, to visit and to speak with them. I am also apprehensive that, upon my return, instead of stopping at my own house, they would make me alight at the barigel (prison); for although this state stands on solid foundations, and enjoys great security, still it is new, and consequently suspicious; nor are there wanting meddling intriguers (*saccenti*), who, like Paul Bertini, would run up a long score, and leave me to pay the reckoning. I beseech you to save me from this danger, and I will by all means come to you at the time I have mentioned. I have been talking with Philip about my little work (the *Prince*), and I have asked him whether it would be proper to give it to the world or not, and, in the event of its being expedient to do so, whether I should bring it myself or send it to you. Were it not published, it is doubtful whether it would ever be read by Julius, and Ardinghelli[2] would reap the honour of this the last of my works. *The necessity which pursues me, however, urges me to give it, because I am wasting away, and cannot long remain thus without becoming contemptible through poverty. My wish is, that these Medici would begin to employ me, were it only at first to roll a stone.* If I did not then gain their good will, I would have myself only to blame; and by this production, if it be read, people will see that, during the fifteen years I passed in studying the art of government, I have not been a careless or inattentive observer; besides, every one should be eager to employ a man who has acquired experience at the expense of others. Of my fidelity no doubt can reasonably be entertained, because, having always acted with good faith, I am not likely now to sacrifice my character. He who has been faithful and good forty-three years, which is my present age, cannot change his nature. *My indigence sufficiently attests my fidelity and uprightness.*"

---

[1] The subject of this *novella piaccevolissima* cannot be better described than in the words of the argument prefixed: "Befagor arcidiavolo è mandato da Plutone in questo mondo, con obligo di dover prender moglie. Ci viene, la prende; e non potendo sofferire la superbia di lei, ama meglio retornarsi in Inferno, che ricongiugnersi seco." Ben Jonson, in the plot of *The Devil is an Ass*, appears to have taken some hints from this tale, with others from Boccacio.

[2] "Out of his surname," says a writer in the *Edinburgh Review* (vol. xlv. p. 260), "they coined an epithet for a knave, and out of his Christian name a synonyme for the devil." For the latter point, the writer has the authority of Hudibras (part iii. canto i.).

Nick Machiavel had ne'er a trick,
Though he gave his name to our Old Nick.

But on this subject the antiquarians, we believe, are by no means agreed.

[3] See preface to the French edition of 1813.

This letter requires no explanation or commentary. In it Machiavelli lays bare his whole soul, disclosing without reserve his vexation, his dread of misery, the shame with which he regarded the almost disgusting situation to which he had been reduced, and his desire at any sacrifice to be again employed in public affairs; nor will the attentive observer, who reads it with care, fail to discover in it a key to the treatise of the *Principe*. Indeed the Italian writers no longer judge of that work without referring to the letter addressed to Vettori.[3] It has been said that Machiavelli, despairing of the liberty of Florence, was inclined to support any government which might secure its independence. But this is a refinement wholly unsupported by evidence. The motive which impelled him to the composition of the work was actual indigence, and the prospect of still greater misery; the object which he sought to attain by it was immediate employment under the new masters of Florence, were it only in the first instance to roll a stone. None of the designs which have been so freely imagined, and so confidently ascribed to the fallen secretary, seems ever to have entered his mind. He wanted bread, and thinking that his book, containing the results of his experience and observation, would be acceptable to a prince, especially a new one, he tenders it through Vettori, in the hope that it might be instrumental in saving him from that destitution, the prospect of which he contemplated with so much horror. It is also to be observed that the book, when first published, did not appear to the Italians in the light in which it was afterwards regarded. This is sufficiently evident from the fact that it was printed in virtue of a privilege granted by Pope Clement VII., dated the 23d of August 1531. Italy was then abandoned to such disorders, that some sovereigns hoped to find useful counsels, where, in point of sound morality, they could meet with nothing but odious precepts. At the same time, if we separate the author from his work, it may be observed, that Machiavelli could not know that his work would ever be published. He composed it in the form of a memoir to Lorenzo de' Medici; and in his dedication to that young prince, he tells him that he has nothing to offer him but the knowledge of the actions of great men, which he had acquired by long experience in modern affairs; and at the close he adds, "If your magnificence, from the elevated station you occupy, would deign to cast an eye on this lower region, you would learn how unjustly I suffer under the great and continual malignity of fortune."[4]

With regard to the general character of Machiavelli as a writer, and also to the particular question, whether the treatise of the *Prince* was a serious production, or, as Bacon seems to suggest,[5] merely a piece of grave irony, intended to put nations on their guard against the arts of new and ambitious princes, we refer the reader to the judicious and discriminating remarks upon both points, contained in the First Preliminary Dissertation (pp. 32–37). The *Prince* is an account of the means by which tyrannical power is to be acquired and preserved; it is a theory of that class of phenomena in the history of mankind. Hence it is essential to its purpose that it should contain an enumeration and exposition of tyrannical arts; and on this account it may not only be viewed, but used, as a manual of such arts. A philosophical treatise on poisons would, in like manner, determine the quantity of each poisonous substance capable of producing death, the circumstances favourable or adverse to its operation, and every other information essential to the purpose of the poisoner, though not intended for his use. But the general utility of such a work is, nevertheless, indisputable; and it is also plain, that a calm unvarnished exposition of tyrannical arts is the bitterest satire against them. Of this Machiavelli himself seems to have been fully aware, when he observed, in reply to a remark which had been made upon this very work, that if he had taught princes to be tyrants, he had also taught the people to destroy tyrants. The *Prince* must, therefore, have had the double aspect here pointed out, though neither of the objects thereby indicated had actually been in the contemplation of the author. It may not be the object of the chemist to teach the means of exhibiting antidotes, any more than of administering poisons; but his pupils or readers may employ his discoveries for both objects. Aristotle had long before given a similar theory of tyranny, but without the suspicion of an immoral intention; nor was it any novelty, in more recent times, amongst those who must have been the first teachers of Machiavelli. The schoolmen followed the footsteps of Aristotle too closely to omit so striking a passage as that to which we have alluded (*Politic.* lib. v. c. 3); and, in fact, Aquinas explains it in his commentary, like the rest, with most unsuspecting simplicity. To us, accordingly, the plan of Machiavelli, like those of former writers, appears to have been purely scientific; and so Lord Bacon seems to have understood him, where he gives him thanks for exposing openly, and without reserve, what princes actually do, not what they ought to do. Great defects of character are no doubt manifested by the writings of Machiavelli. But if a man of so powerful a genius had shown a mind utterly depraved, it would have been a painful and perhaps solitary exception to the laws of human nature; and certainly no depravity can be conceived greater than a deliberate intention to teach perfidy and cruelty. That a man who was a warm lover of his country, who underwent cruel sufferings for her liberty, and who was esteemed by the very best of his countrymen (*e. g.* Guicciardini, his political opponent), should fall into such unparalleled wickedness, may be considered as wholly incredible. The author of the *Prince*, according to the common notion of its intention, could never have inspired such sentiments, had he been a man steeped in depravity, and devoid of all virtuous feeling. To possess the power, however, of contemplating tyranny with scientific coldness, and of rendering it the mere subject of theoretical speculation, must be owned to indicate a defect of moral sensibility. But, to say nothing of the political maxims then received, and of the lenity with which the Italians regarded those crimes which required self-command, address, quick observation, fertile invention, and profound knowledge of human nature, the *Prince* was obviously wrung from the author by the pressure of severe distress; and it is more than probable, that, but for his misfortunes, this famous treatise would never have seen the light.[1]

---

[1] In point of fact, it is dedicated to the young Lorenzo de' Medici, duke of Urbino, and brother-in-law of Strozzi.

[2] Nicolas Ardinghelli, distinguished for his acquirements in Greek and Roman literature, died a cardinal at Rome in 1547.

[3] On this question, and on other important points relative to Machiavelli, the reader may consult the excellent dissertation of the Chevalier Baldelli.

[4] Et se vostra Magnificenza dallo apice della sua Altezza, qualche volta volgerà gli occhi in questi luoghi bassi, conoscerà quanto indegnamente io sopporti una grande e continua malignità di Fortuna."

[5] "Est quod gratias agamus Machiavello et hujusmodi scriptoribus, qui aperte et indissimulanter proferunt quid homines facere soleant, non quid debeant." (*De Augment. Scient.* lib. viii. c. 2.)

The most ample and esteemed edition of the works of Machiavelli is that of 1813, *Italia* (Florence), in eight vols. 8vo. The best of the French translations is that of Giraudet and Hochet, Paris, 1799, in nine vols. 8vo. Those of Gohorry, Paris, 1571 and 1635, of the Sieur de Briencour, Rouen (Paris), 1669, and of Tétard, Hague, 1691–1696, reprinted in 1743, were very incomplete. The only English translation to which we have had access is that of Farneworth, London, 1762, in two vols. 4to, which is overloaded with a great deal of rubbish that might well have been spared, and is, besides, defective in several respects, particularly in regard to the life of the author, and some of his minor productions. (A.)

MACHINE, *Machina*, in general signifies any thing that serves to augment or to regulate moving powers; or it is any body destined to produce motion, so as to save either time or force. The word comes from the Greek *μαχανη*, *machine*, *invention*, *art*; and hence, in strictness, a machine is something that consists more in art and invention than in the strength and solidity of the materials, for which reason inventors of machines are called *ingénieurs*, or *engineers*. Machines are either simple or compound. The simple ones are the seven mechanical powers, namely, the lever, balance, pulley, axis and wheel, wedge, screw, and inclined plane. See MECHANICS.

MACHINERY, in epic and dramatic poetry, is when the poet introduces some supernatural being into the scene, in order to solve some difficulty, or to perform some exploit out of the reach of human power. The ancient dramatic poets never made use of machinery, unless where there was an absolute necessity for so doing. It is quite otherwise with epic poets, who introduce machinery in every part of their poems; so that nothing is done without the intervention of the gods. In Milton's *Paradise Lost*, by far the greater part of the actors are supernatural personages. Homer and Virgil do nothing without them; and, in Voltaire's *Henriade*, the poet has made excellent use of St Louis.

MACHTEBETE, a town of the Netherlands, in the province of East Flanders and circle of Ghent, situated on the Moerdeke-Baert, containing 3350 inhabitants.

MACHUL, a musical instrument amongst the Hebrews. Kircher apprehends that this name was given to two kinds of instruments, one of the stringed, and the other of the pulsatile kind. That of the former sort had six chords; but there is great reason to doubt whether an instrument requiring the aid of the hair-bow, and so much resembling the violin, be as ancient as this would imply. The second kind was of a circular form, made of metal, and either hung round with little bells, or furnished with iron rings suspended on a rod or bar which passed across the circle. Kircher supposes that it was moved to and fro by a handle fixed to it, and thus emitted a melancholy kind of murmur.

MACHYNLETH, a market-town of Wales, in the county of Montgomery and hundred of its own name, 200 miles from London. It stands on the river Dyvy. It is a neat, well-built town, and very ancient, being the place where Owen Glendower assembled his parliament, and exercised other acts of regality, in the year 1402. The market is held on Monday. It is an ancient borough, and, in conjunction with Llanidloes, Llanvilling, Welshpool, and Newton, returns one member to parliament. The population amounted in 1801 to 1118, in 1811 to 1252, in 1821 to 1595, and in 1831 to 1625.

MACKENHEIM, a town of the circle of Rheinbach, in the Prussian government of Cologne, situated on the river Erft, containing 200 houses and 1260 inhabitants.

MACKENZIE, SIR GEORGE, a learned writer and eminent lawyer of Scotland, was the grandson of Kenneth, first Lord Mackenzie of Kintail, and the nephew of Colin and George, first and second Earls of Seaforth. He was born at Dundee in 1636; and after passing through the usual course of education in his own country, he was sent to the university of Bourges, at that time denominated the Athens of lawyers, where he remained three years. Young Scotchmen intended for the bar, having no sufficient means of instruction in the Roman law at home, were then accustomed to frequent the university of Bourges, as in later times they repaired to those of Utrecht and Leyden. He was called to the bar in the year 1656, and had risen into considerable practice before the Restoration. In a sketch of an eminent advocate of that day, he has recorded his contempt for the canting tone which then prevailed in the courts of law, and to which even the most learned advocates, whatever their own inclinations might have been, were obliged to conform.[1] Immediately after the Restoration he was appointed one of the justices-depute, criminal judges who exercised that jurisdiction which was soon afterwards vested in five lords of sessions, under the denomination of commissioners of justiciary; and, in 1661, he and his colleagues were ordained by the parliament " to repair, once in the week at least, to Musselburgh and Dalkeith, and to try and judge such persons as are ther or therabouts delate of witchcraft ;" so much more urgent did they deem the punishment of that imaginary offence than of any other crime, however aggravated.

---

[1] See *Edinburgh Review*, vol. xxvii. pp. 213, 214.

Mackenzie's name appears in the parliamentary proceedings as counsel in almost every cause of importance; and his connection in that character with the Marquis of Argyll gives no small weight to a passage in his *Memoirs*, respecting a circumstance in the trial of that nobleman, which has been the subject of much historical controversy. Between the years 1663 and 1667 he was knighted. He represented the county of Ross during the four sessions of the parliament which was called in 1669. In 1667, he had been appointed lord advocate in the room of Sir John Nisbet, whom he describes, in one place, as " a person of deep and universal learning," and of whom, in another, he says, that " in the conduct of causes he displayed the greatest learning and consummate eloquence."[2] By that preferment he was, unhappily for his character, implicated in all the worst acts of the Scotch administration of Charles II.; a system of misgovernment which has only had one parallel in the European portion of the British dominions. Having betrayed some repugnance, however, to concur in those measures which openly and directly led to the re-establishment of popery, he was removed from his office in 1686, and (which is not a little remarkable) reinstated in 1688, when such measures were still more avowedly pursued.

At the Revolution he adhered to the fortunes of his royal master. Being elected a member of the convention, he supported the pretensions of King James with courage and ability, against Sir John Dalrymple and Sir James Montgomery, who were the most considerable speakers of the Revolution party; and remaining in his place even after the imprisonment of Balcarras and the escape of Dundee, he was one of the minority of five in the memorable division respecting the forfeiture of the crown.[3] King William had been solicited, by some eager partisans, to declare Mackenzie and a few others incapable of holding any public office; but he refused to accede to the proposal, in conformity to the maxims of that wise policy, which uniformly induced him not to concur in those measures, even of just retribution, which, at moments of violent internal change, are so apt to degenerate into proscription and revenge. At this critical juncture, when the crown, which one king was declared to have forfeited, was placed on the head of another, and when his own fortunes were in jeopardy, Sir George Mackenzie composed and delivered his inaugural address on the foundation of the library of the Faculty of Advocates; a circumstance evincing no inconsiderable degree of firmness and intrepidity. When the death of Dundee destroyed the hopes of his party in Scotland, he took refuge in Oxford, the natural asylum of so learned and inveterate a Tory. But, under the tolerant government of King William, he appears to have enjoyed, in perfect security, his ample fortune, the fruit of his professional labours. In Evelyn's Diary (9th March 1690), we have an account of the freedom which he indulged in conversation at the table of a prelate who was a zealous supporter of the new government. " I dined," says he, " at the Bishop of St Asaph's, almoner to the new queen, with the famous lawyer Sir G. Mackenzie (late lord advocate of Scotland), against whom both the bishop and myself had written and published books, both now most friendly reconciled. He related to us many particulars of Scotland, the present sad condition of it, the inveterate hatred which the presbyterians show to the family of the Stewarts, and the exceeding tyranny of those bigots, who acknowledge no superior on earth in civil or divine matters, maintaining that the people only have the right of government, their implacable hatred to the Episcopal order and the Church of England. He observed, that the first presbyter dissents from our discipline were introduced by the Jesuits about the twentieth of Elizabeth; a famous Jesuit among them feigning himself a Protestant, and who was the first who began to pray extempory, and brought in that which they since called, and are still so fond of, praying by the Spirit."[4]

In the spring of 1691, Sir George Mackenzie went to London, where he contracted a disorder which carried him off. He died in St James's Street, on the 2d of May 1691; and his death is mentioned as that of an extraordinary person, by several of those who recorded the events of their time. His body was conveyed by land to Scotland, and interred with great pomp and splendour in Edinburgh; a circumstance which shows how little the administration of William was disposed to discourage the funeral honours paid to its most inflexible opponents. It may also be mentioned, to the honour of the government, that, whilst the censorship of the press still subsisted, he was allowed to publish his Vindication of the Government of Scotland under Charles II.; a very inadequate defence, it must be owned, but one, nevertheless, which a new prince, opposed by a powerful party in the state, had some reason to dread.

The writings of Sir George Mackenzie are literary, legal, and political. His Miscellaneous Essays, both in prose and verse, may now be dispensed with, or laid aside, without difficulty. They have not vigour enough for long life; but, considered as the elegant amusements of a statesman and lawyer, they afford evidence of the refinement of his taste and the variety of his accomplishments. In several of his moral essays, both the subject and the manner betray an imitation of Cowley, who was at that moment commencing the reformation of English style. Like his master, he wrote in praise of solitude; and Evelyn, in a confidential letter to Cowley, highly commends his merits as a writer. Nor would it be just to the memory of Mackenzie to refrain from mentioning the extraordinary praise bestowed on him by Dryden, the successor, but scarcely the superior, of Cowley, in English prose.

Sir George Mackenzie is one of the few British advocates who have published their speeches delivered at the bar. In Scotland these are often called " pleadings," and in England " arguments," when addressed to the judges on matters of law; but they retain the general name of " speeches" when addressed to a jury, or to any other popular body.

[1] " Nicholsonus junior eloquio usus est fanatico non Romano; et hinc concionabatur potius quam orabat: documentum posteris futurus, illud ad persuadendum aptius quod sæculo, licet sordido, et judicibus, licet hebetioribus placet. Si autem doctus hic orationes posteris transmisisset, Augusti sæculum, illi notissimum, imitatus fuisset." (*Characteres quorundam apud Scotos Advocator.*)

[2] See *Memoirs*, p. 324. " Qui summa doctrina consummataque eloquentia causas orabat." (*Characteres quorund. Advocat.*)

[3] Balcarras *Memoirs*, in MS.

[4] Evelyn's *Memoirs*, vol. ii. p. 19. The absurd fictions, so gravely reported in the above extract, seem to countenance the supposition that Sir George Mackenzie, knowing his men, had been making an experiment on their credulity, and hoaxing both the bishop and Evelyn. It is wonderful indeed that he did not represent John Knox as a disguised jesuit.

Mackenzie's speeches evince considerable knowledge, ingenuity, and address, and are never very defective except in those passages which aim at eloquence. In the speech before the parliament for the Marquis of Argyll, the question, whether passive compliance in public rebellion be punishable as treason, is treated with no small ability.

His work on the Laws and Customs of Scotland in Matters Criminal was published in 1678, and is dedicated to the Duke of Lauderdale, to whom the author says, "You are yourself the greatest statesman in Europe who is a scholar, and the greatest scholar who is a statesman. You are the man who spends the one half of the day studying what is just, and the other half in practising what is so!" At that time the government of Scotland had no reason to complain of the want of base compliance in juries, not one of which, during the eighteen years that had elapsed since the Restoration, had ventured to rescue a single victim, however innocent, from the clutches of power. But, even in the midst of this apparent security, the acuteness of the Lord Advocate discovered the possibility that independent juries might one day arise; he augured integrity at a distance, scenting the approach of liberty in every refreshing gale; and hence, in the work just named, he openly proposes the abolition of juries in criminal causes.[1] His reasonings are ingenious and plausible. He tells us, that "now, when law is formed into a science, and that judges are presumed to be learned and assizers not, it seems reasonable they should be suppreſt, as well in criminal cases as they already are in civil." The great and paramount benefit of juries in criminal cases, namely, their power of shielding innocent and virtuous men against the vengeance of power, is kept entirely out of view, though doubtless it formed the sole motive for the project.

The works of Sir George Mackenzie were published at Edinburgh in two volumes folio, in 1716 and 1722. In the second volume there appears the following advertisement: "Whereas in the list of the author's manuscripts there is mention made of an History of the Affairs of Scotland from the Restauration of King Charles II. 1660, to the [year] 1691, which subscribers might have readily looked for in this second volume; but that manuscript being in the hands of some of the author's relations, who think it not ready for the press until it be carefully revised, they have reckoned it more proper to have it printed by way of Appendix to this second volume, how soon they have it revised and transcribed by a good hand." For many years the History thus announced was supposed either to have perished or to have been intentionally destroyed. The second Earl of Bute, who supported the government of the House of Hanover, and had married the sister of John duke of Argyll, the leader of the Whig party in Scotland, enjoyed, in the year 1722, and probably possessed, his papers. It was not unnatural, therefore, that he should be suspected, at that juncture, of suppressing such a manuscript, more especially as his family, by conforming to the Revolution, and accepting a title from Queen Anne, had rendered themselves peculiarly obnoxious to the adherents of the House of Stuart. But, however plausible these conjectures may have appeared, they have, in part at least, been proved to be groundless. In the year 1817, a large mass of papers was sold to a shopkeeper in Edinburgh. From these his curiosity led him to select a manuscript volume which appeared to him to be something of an historical nature; and, by another fortunate accident, he communicated it to the late Dr M'Crie, who, on examination, discovered that it was the composition of Sir George Mackenzie, and formed part of that history of his own times which had so long been a desideratum in Scottish literature. Of this the evidence was both obvious and complete; for the manuscript, though written by one of the ordinary transcribers of that age, was decisively identified by numerous corrections and additions in the well-known handwriting of Sir George Mackenzie himself. The curious fragment of Scottish history, thus happily recovered, was published at Edinburgh in 1821, 4to, under the editorial superintendence of Mr Thomas Thomson, who, in an able and well-written preface, has related the singular circumstances in which the manuscript was rescued from destruction. It is to be regretted, however, that the portion thus published ends at the very time when the author's means of information became more ample. For many reasons, it would be highly desirable to possess the sequel of these Memoirs.[2] (A.)

MACKENZIE, *Henry*, was born at Edinburgh, in August 1745. His father, Dr Joshua Mackenzie, was an eminent physician of Edinburgh, the author of a volume of Medical and Literary Essays; his mother was the eldest daughter of Mr Rose of Kilravock, of an ancient family in Nairnshire.

After being educated at the High School and University of Edinburgh, Mr Mackenzie was articled to Mr Inglis of Redhall, to qualify him for exchequer business. In 1765 he went to London to study the modes of English exchequer practice. Whilst there, his talents induced a friend to solicit his remaining in London to qualify himself for the English bar; but the wishes of his family, and the moderation of his own unambitious mind, decided his return to Edinburgh; and there he became, first partner of, and afterwards successor to, Mr Inglis, in the office of attorney for the crown. When in London, he sketched some part of his first and very popular work, *The Man of Feeling*, which was published anonymously in 1771. The great popularity of this volume gave occasion to a remarkable fraud on the part of a Mr Eccles of Bath, who, taking advantage of the book being anonymous, laid claim to the authorship, transcribed the whole in his own hand, with interlineations and corrections, and maintained his right with such plausible pertinacity, that Messrs Cadell and Strahan, Mr Mackenzie's publishers, found it necessary to undeceive the public by a formal contradiction. The *Man of the World* was published a few years after the *Man of Feeling*, and breathes the same tone of exquisite sensibility. In his first publication he imagined a hero constantly obedient to every emotion of his moral sense. In the *Man of the World* he exhibited, on the contrary, a person rushing headlong into vice and ruin, and spreading misery all around him, by grasping at happiness in defiance of the moral sense. His next production was *Julia de Roubigné*, a novel in a series of letters. The fable is very interesting, and the letters are written with great elegance and propriety of style. In 1777 or 1778, a society of gentlemen in Edinburgh, mostly lawyers, projected the publication of a series of papers on morals, manners, taste, and literature, similar to those of the *Spectator*. This society, originally designated The Tabernacle, but afterwards The Mirror Club, consisted of Mr Mackenzie, Mr Craig, Mr Cullen, Mr Bannatyne, Mr Macleod, Mr Abercrombie, Mr Solicitor-General Blair, Mr George Home, and Mr George Ogilvie, several of whom afterwards became judges in the Supreme Courts of Scotland. Their scheme was speedily carried into effect, and the papers, under the title of the *Mirror*, of which Mr Mackenzie was the editor, were published in weekly numbers, at the price of threepence per folio sheet. The sale never reached beyond three or four hundred in single papers; but the whole, with the names of the respective authors, were republished in three duodecimo volumes. From the price of the copyright, the writers presented a donation of L.100 to the Orphan Hospital, and purchased a hogshead of claret for the use of the club. To the *Mirror* succeeded the *Lounger*, a periodical of a similar character, and equally successful. Mr Mackenzie was the most valuable contributor to both these works. His papers are distinguished from all the rest by that sweetness and beauty of style, and tenderness of feeling, which form the peculiar character of his writings. In the *Lounger* Mr Mackenzie was the first to appreciate the genius of Burns, in a review of his poems, then recently published, which at once drew the unknown poet from obscurity into the full blaze of a fame that will never die. On the institution of the Royal Society of Edinburgh, Mr Mackenzie became one of its members; and amongst the papers with which he enriched the volumes of its Transactions are, an elegant tribute to the memory of his friend Judge Abercrombie, and a memoir on German Tragedy, the latter of which bestows high praise on the *Emilia Galotti* of Lessing, and on the *Robbers* by Schiller. Whilst prosecuting his study of German literature, he was induced to publish, in the year 1791, a small volume containing translations of the Set of Horses by Lessing, and of two or three other dramatic pieces. Mr Mackenzie was one of the original members of the Highland Society, and wrote the accounts of the institution and principal proceedings of the society which appear in their Transactions. In the Transactions of the same society he published a view of the controversy respecting the poems of Ossian, in which he attempted to vindicate their authenticity; and in the same paper gave a spirited and interesting account of Gaelic poetry. In 1793 he wrote the Life of Dr Blacklock, prefixed to the quarto edition of the works of the blind poet. In 1812 he read to the Royal Society a memoir of John Home, in which he gives a sketch of the literary society of Edinburgh during the latter part of the last century, with the great ornaments of which he lived in habits of friendly intercourse.

---

[1] Part ii. title 23, of Assizes.

[2] See *Edinburgh Review*, vol. xxxvi. p. 1, *et seq.* from which the foregoing notice is almost exclusively derived.

Mr Mackenzie was not so fortunate as a writer of dramas. Several of his plays were brought out at different theatres, but, though possessed of considerable merit as literary productions, they were not successful on the stage. He wrote several political tracts, which procured him the countenance and respect of Mr Pitt, and other illustrious statesmen of his time. Mr Mackenzie was not more distinguished by the wit with which he enlivened a numerous circle of attached friends, than the benevolence and wisdom with which he counselled and assisted them. This ornament of his native city died at Edinburgh, at an advanced age, rather from the decay of nature than from disease, on the 14th of January 1831.

A complete edition of his works was published at Edinburgh, in eight volumes 8vo, in 1808.

MACKINTOSH, THE RIGHT HONOURABLE SIR JAMES, one of the most distinguished men of his time, and who attained to great eminence in literature, philosophy, history, and politics, was born at Aldourie, on the banks of Loch Ness, Scotland, on the 24th of October 1765. His father, Captain John Mackintosh, was the representative of a family which had for above two centuries possessed a small estate called Kellachie, in Inverness-shire. He had served long in the army, which he entered very young, and had been severely wounded at the battle of Felinghausen, in the Seven Years' War. His mother was Marjory Macgillivray, daughter of Mr Alexander Macgillivray by Anne Fraser, sister of Brigadier-General Fraser, who was killed in General Burgoyne's army in 1777. His father joined his regiment at Antigua soon after his birth, and remained in that island and in Dublin for eight or nine years. He was reared with great care and tenderness by his mother, notwithstanding the anxiety and discomfort incident to the condition of one who had no available resources of her own. His father, a subaltern and younger brother, found his pay not too much for his own expenses; and all the kindness of his mother's family could not relieve the mind of that lady from the painful, not to say humiliating, sense of dependence. This probably contributed to the extreme affection which she cherished for her child. He depended upon her alone; and as there is nothing which so much lightens the burden of receiving benefits as the pleasure of conferring them, she loved him "with that fondness which we are naturally disposed to cherish for the companion of our poverty."

In the summer of 1775, young Mackintosh was sent to school at the town of Fortrose, where he was placed under a master of the name of Smith. In a short memoir of this early period of his life, he says, "I have little recollection of the first two years at school;" but he had scarcely learned to read when he evinced that predilection for abstract speculation which afterwards formed so prominent a feature of his intellectual character. A gentleman of the name of Mackenzie having lent him Burnet's Commentary on the Thirty-nine Articles, he perused it with great avidity; "and I have now," says he, writing many years afterwards, "a distinct recollection of the great impression which it made." But the part which struck him most forcibly, and which he read with peculiar eagerness and pleasure, was the commentary on the seventeenth article, which relates to predestination; a strange subject to engage the attention and interest the understanding of a mere boy. "I remember," says he, "Mr Mackenzie pointing out to me, that though the bishop abstained from giving his own opinion on that subject in the commentary, he had intimated that opinion not obscurely in the preface, when he says that 'he was of the opinion of the Greek church, from which St Austin departed.'" He was of course profoundly ignorant of what the Greek church was, and knew nothing of St Austin's deviations; but the mysterious magnificence of this phrase had an extraordinary effect upon his imagination. His mind appears to have revolted at the doctrine of eternal decrees of election and reprobation; though surrounded by orthodox Calvinists, he became a warm advocate for free will; and before he had completed his fourteenth year, he was probably the boldest heretic in the county. About the same time he read the old translation of Plutarch's Lives, and Echard's Roman History, which led him into "a ridiculous habit," which afterwards clung to him, of building castles in the air. During his vacations, which he spent at his grandmother's house, he read such books as fell in his way, and amongst these the works of Pope and Swift. His first poetical attempt was a pastoral or elegy on the death of his uncle Brigadier-General Fraser, who fell on the 7th of October 1777; but in 1779 and 1780 his muse was exceedingly prolific, and he even commenced an epic poem on the defence of Cyprus by Evagoras, king of Salamis, against the Persian army.

In October 1780 he went to college at Aberdeen, where he remained during that and the three following sessions. On entering King's College, he was admitted into the Greek class, then taught by Mr Leslie, who, however, did not attempt to do more than teach the first rudiments of the language. The second winter, according to the scheme of education then pursued, he fell under the tuition of Mr Dunbar,[1] and remained under the care of this gentleman until he left college. At Aberdeen he was by common consent recognised as *inter studiosos facile princeps;* whilst his courteous demeanour, refined manners, playful fancy, and easy flow of elocution, rendered him a general favourite amongst his companions. His chief associate at King's College was the late Reverend Robert Hall, whom the exclusive system of the English universities had forced to seek, in this northern seminary, for that academical education which was denied to him, as a dissenter, in his own country. Like Castor and Pollux, these young men were assimilated in the minds of all who knew them, by reason of the equal splendour of their talents, although in other respects they were extremely unlike. They were of the same intellectual stature, but differently moulded; the one being remarkable for gracefulness of manners and symmetry of powers, with much elegance and refinement; the other plainer, and withal less polished, but distinguished for perfect sincerity, ardent piety, and undeviating love of truth. The society and conversation of Hall had great influence on Mackintosh's mind. Their controversies were almost unceasing. Even at this early period, Hall "displayed the same acuteness and brilliancy, the same extraordinary vigour both of understanding and imagination, which have since distinguished him, and which would have secured to him much more of the admiration of the learned and the elegant, if he had not consecrated his genius to the far nobler office of instructing and reforming the poor."

---

[1] Author of *Essays on the History of Mankind.*

In the spring of 1784, having previously taken his degree of master of arts, he finally quitted King's College, "with," he says, "but little regular and exact knowledge, but with considerable activity of mind, and boundless literary ambition;" and in the October following he set out for Edinburgh to commence the study of physic, which he had made choice of as a profession. His arrival in that city opened a new world to his mind. Edinburgh was then the residence of many eminent men; of Adam Smith, Dr Black, John Home, Henry Mackenzie, Dr Cullen, Principal Robertson, Dr Ferguson, Dr Hutton, Professor Robison, Mr Dugald Stewart, and others; and although his age did not allow him to be much acquainted with these celebrated persons, yet accident furnished him with opportunities of access to some of them, whilst the concentration of so much genius and talent produced a powerful impression on his ardent and susceptible nature. His speculative turn of mind, however, soon betrayed itself. Within a few weeks after his arrival in Edinburgh, he became a zealous partisan of Brown, who had just become a teacher of medicine, and the founder of a new medical system; and having been elected a member of the Medical Society, he, in a few months, "before he could have distinguished bark from James's powder, or a pleurisy from a dropsy in the chamber of a sick patient," discussed with the utmost fluency and confidence the most difficult questions in the science of medicine. But he had soon an opportunity of displaying his peculiar talents on a theatre better fitted for the exercise of his powers. He was admitted a member of the Speculative Society, which had been established about twenty years before, and, during that period, numbered amongst its members all the distinguished youth in Scotland, besides many foreigners attracted to Edinburgh by the fame of its medical school. In this society, which had general literature and science for its objects, he found some congenial spirits, of whom he has left very graphic sketches, particularly Malcolm Laing the historian, John Wilde, afterwards professor of the civil law in the university of Edinburgh, Benjamin Constant, Adam Gillies, now Lord Gillies, and several other young men, who afterwards rose to eminence or attained distinction in different pursuits. In this exciting atmosphere, speculation rather than study engrossed his attention. Youth, the season of humble diligence and laborious application, was wasted, as he himself complains, in vast, vain, and fruitless projects. Speculators indeed are seldom submissive learners. Those who will make proficiency in useful knowledge, must for a time trust to their teachers, and believe in their superiority; but those who too early think for themselves must sometimes imagine themselves wiser than their masters; and hence docility is often extinguished when the work of education is scarcely commenced. After three years spent in irregular application, he became a candidate for a degree; and having obtained his diploma, he quitted Edinburgh in the month of September 1787, with a large stock of miscellaneous information, acquired by habitual though desultory reading, but without having concentrated his powers upon any one pursuit, or given to professional subjects that systematic and methodical attention which is indispensable to the attainment of professional eminence.

Early in 1788, he set out for London, accompanied by one of his college friends, and arrived on that great theatre of action at a moment sufficiently distracting for one of more advanced age and more settled pursuits. An ardent enthusiast for political amelioration, he came in contact with society when it was already heaving with the first throes of that great convulsion which was soon to overturn all the institutions of a neighbouring country, and to shake those of every other to their lowest foundations. To a young man like Mr Mackintosh, a period of such excitement had irresistible allurements. He had cultivated habits of public speaking, both at Aberdeen and at Edinburgh; he was fond of moral and political controversy, rather perhaps as an exercise of the reasoning powers than with any view to the formation of settled opinions; he found, on the subject of politics, the boldest speculations in which his mind had been engaged, about to receive a practical application; and he longed to mingle in the discussions, if not to take part in the scenes, which distinguished that memorable time. Still his views were, in the first instance at least, directed to the medical profession; and he was led from circumstances to contemplate a medical appointment in Russia. But this project, in which he was supported by Mr Dugald Stewart, did not take effect; and it is probable that he felt but little regret at the failure of a scheme which would have removed him from such a scene of interest and enjoyment as London then presented. In the same year, his father's death freed him from the little control which a soldier of careless and social habits had attempted to exercise over a studious youth; and, as the succession to his paternal estate of Kellachie brought with it but little advantage to his means, his habitual profusion in money matters soon involved him in pecuniary difficulties. His next step was one which seemed but little calculated to diminish them. On the 18th of February 1789, he was privately married to Miss Catharine Stuart, a young lady of a respectable Scotch family; and at the age of twenty-four he found himself with no prospect of any immediate professional settlement, his little fortune rapidly diminishing, and a wife to provide for.

The struggle regarding the regency that followed the announcement of the malady with which the king had been attacked in the autumn of 1788, was the occasion of a pamphlet by Mr Mackintosh, in support of the analogy which Mr Fox endeavoured to establish between the actual state of his majesty and a natural demise of the crown. This seems to have been his first public appearance in the field of politics, for which his mind had now taken a decided turn. About the same time he made the acquaintance of Horne Tooke, whose cause he warmly espoused at the election for Westminster, and in whose rich and lively but sarcastic conversation, he always took great delight. Another effort to establish himself in practice as a physician proved unavailing, probably from his distaste for his profession, and his unwillingness to leave London, which he considered as the grand theatre for talent and ambition. In the autumn of 1789, he made a tour, in company with his wife, through the Low Countries to Brussels; and, upon his return to London, contributed a number of articles on Belgium and France to the *Oracle* newspaper, with which he appears to have been for some time connected. To the same date must be referred his resolution to devote himself to the study of the law. Hitherto the exercise of his powers had been almost exclusively confined to the columns of a newspaper; but although the most successful efforts of ability are often passed unheeded, or make but a feeble and transitory impression where such are neither looked for nor expected, yet this preliminary training was not without its advantage, and the time now approached when he was to appear before the world in a higher and more independent character.

The extraordinary impression produced by the publication of Mr Burke's *Reflections on the French Revolution*, the admiration excited by the work in some quarters, and the vehement indignation with which it was greeted in others, are matters of universal notoriety. By some it was regarded as the most marvellous union of wisdom and genius that had ever appeared in the world, whilst to others it seemed inconsistent with the former life and opinions of the author, notwithstanding that an abhorrence for abstract politics, a predilection for aristocracy, and a dread of innovation, had always been articles of his political creed. The former magnified the sense of public duty which prompted, first the sacrifice of the long-cherished friendship of Mr Fox; and then the publication of what they considered as the earnest admonitions of matured wisdom. The latter, mistaking the real principles of the author, imputed to him an inconsistency with which he was not really chargeable; and, whilst they endeavoured to refute his reasonings and deride his prognostications, branded him as a deserter of the principles he had once professed. The number of antagonists who hurried to break a lance against the champion of existing institutions proved the estimation in which he was held; a multitude of pamphlets appeared, and each shade of opinion was warmly defended against the common enemy of all change. The great majority of these productions, however, soon fell into oblivion. But Paine's *Rights of Man* was not destined to perish so speedily. His strong sense, bold dogmatism, and coarse but vigorous sarcasm, conveyed in a style instinctively popular, made him a dangerous enemy at all times, but more especially at a period when the new principles of liberty had found favour with the people, and when the great masses of the middle and lower orders were to be appealed to in defence of them. But whilst Mr Burke was sustaining the attack of the man who had been his fellow-combatant in the American contest for freedom, " a bolt was shot from amongst the undistinguished crowd, but with a force which showed the vigour of no common arm." The *Vindiciæ Gallicæ* was published in April 1791. It had been finished in a great hurry, but, with all its imperfections and defects, it at once placed the author in the first rank of the party in this country who were upholding the cause of France. He was courted and caressed on all hands, his company was eagerly sought for, and, as he himself expressed it, he was for a few months the lion of the place. In the mean time, the sale of the book exceeded his most sanguine expectations; three editions followed one another with great rapidity; it was quoted in the debates in parliament, eulogised by Mr Fox, and even commended by Mr Burke, for whose genius Mr Mackintosh entertained a chivalrous admiration. In a word, the execution of the work answered every expectation which had been formed of the author; and though he saw occasion afterwards to modify some, if not many, of the opinions expressed in it, yet it is impossible not to acknowledge that it deserved the favour and applause with which it was received by the friends of popular liberty.

In Michaelmas term 1795, Mr Mackintosh was called to the bar, and attached himself to the home circuit. Having thus entered upon a path which, when pursued by the patient steps of genius and industry, so often leads to wealth and distinction, he evidently enjoyed the satisfaction which arises from having in view a constant and honourable occupation. But a severe affliction awaited him in the death of his wife, which took place early in 1797; whilst slowly recovering from the birth of a child, Mrs Mackintosh was attacked by a fever, to which she soon fell a victim, leaving three daughters. In 1799 Mr Mackintosh formed the plan of giving lectures upon the law of nature and of nations. The benchers of Lincoln's Inn granted him the use of their hall, and he commenced his course by an exposition of the general aim and scope of the undertaking, as well as of the views and feelings which had led him to embark in it. In the introductory lecture, after an eloquent vindication of the term " law of nature," and a review of the works of the different masters of the science, exhibiting its progress (in which the character of Grotius is delineated in a manner worthy of his great learning and genius), the subject is marked out into six great divisions, viz. *first*, an analysis of the nature and operations of the human mind; *secondly*, the relative duties of private life; *thirdly*, the relations of subject and sovereign, citizen and magistrate, the foundation of political liberty and political rights; *fourthly*, the municipal law, civil and criminal, exemplified by the progress of the codes of Rome and of England; *fifthly*, the law of nations strictly so called, or the science which regulates the application of the sanctions of private morality to the great commonwealth of nations; and, *lastly*, a survey of the diplomatic and conventional law of Europe. This discourse, which the lecturer was induced to publish, had no sooner issued from the press than commendations poured in upon him from every quarter. Mr Pitt, Lord Loughborough, Dr Parr, and others, united their suffrages in its praise; and it must be confessed, that if Mackintosh had published nothing else than this discourse, he would have left a striking monument of his intellectual strength and symmetry. His political opinions, indeed, had undergone a considerable change, and as the tone of these lectures differed materially from that of the *Vindiciæ Gallicæ*, and of the *Letter to Mr Pitt*, this circumstance, together with the support ostentatiously given to them by the ministers of the day and their connections, served to alienate from him several of his old political friends, and to beget suspicions for which there existed no solid foundation. At the same time, it may be conjectured that the friendship and correspondence of Mr Burke, and the warm commendations of Mr Pitt, may have unconsciously had some influence on his mind; and that the change to which we have alluded, and which he himself was too honest not to acknowledge, may not be altogether imputable to horror at the excesses which disgraced the cause of liberty in France, and disappointment at not seeing it established so speedily and purely as he had anticipated.

We come now to an event of great importance in the life of Mr Mackintosh; we mean the trial of M. Peltier, an emigrant royalist, for a libel on the First Consul of France. The circumstances which led to this memorable trial, the extreme novelty or rather singularity of the case, its immediate connection with the state of political feeling which then prevailed, and the importance which was generally attached to the result, are too well known to require any specification in this place. It is sufficient to observe, that the address delivered by Mr Mackintosh, as counsel for the accused, formed one of the most splendid displays of eloquence ever exhibited in a court of justice, and that it will, beyond all doubt, maintain its place amongst the few efforts of forensic oratory which have survived the occasions that produced them, and are preserved as models for future artists in the same line. "I perfectly approve of the verdict," said Mr, afterwards Lord Erskine; "but the manner in which you opposed it, I shall always consider as one of the most splendid monuments of genius, learning, and eloquence." Similar testimonies of applause were bestowed by other distinguished persons; and it was admitted on all hands, that, by this single effort, Mr Mackintosh had suddenly raised himself to the very highest rank amongst forensic orators. This trial took place on the 21st of February 1803, and, some months afterwards, Mr Mackintosh was appointed to the office of recorder of Bombay, vacant by the death of Sir William Syer. Mr Addington, the first minister of the crown, had been previously made acquainted with Mr Mackintosh's wishes in relation to an appointment in India; and these were now seconded by the friendly zeal of Mr Canning and Mr (afterwards Lord Chief Commissioner) Adam, to whose exertions the appointment must in a great measure be attributed. In taking this step, he was probably influenced by two considerations; first, the comparative ease which it would immediately secure to him; and, secondly, the amount of the salary, which, he believed, might in a few years enable him (as it would if prudence had been amongst the number of his virtues) to accumulate a sum which, in addition to the retired allowance, would render him independent, give him the entire command of his time, and enable him to pursue the course of life best suited to his inclinations. But the hopes of men are often as vain as their calculations are sanguine, and outrun even the consciousness of their own failings. Upon his appointment, he received the customary honour of knighthood, and, early in 1804, sailed with his family for India.

For an account of his life during the eight years which he spent in India, it is only necessary to refer the reader to the Memoirs of his Life, published by his son; a work which, independently of the interest attaching to the principal subject, will be read with instruction and delight on account of the infinite variety of original thoughts and fine observations with which it abounds. His time, indeed, appears to have been divided between the discharge of his judicial duties, literary occupations somewhat irregularly pursued, correspondence with his numerous friends in Europe, and occasional excursions into different parts of the country. The experiment, however, was not successful, in as far as regarded the views which had induced him to solicit the appointment. For, although we now know that his mind was in a state of great vigour and activity during the whole of his residence in India, yet he was not enabled to accomplish, indeed scarcely to commence, any of the great works he had contemplated; whilst his habitual inattention to economy prevented any great improvement in the state of his worldly affairs. The consequence was, that he returned to England in 1812, with broken health and spirits, uncertain prospects, and vast materials for works which were never to be completed.

Mr Percival was now at the head of the government, and, almost immediately on his arrival, endeavoured to secure the support of Sir James, by offering him a seat in parliament, and an early promotion to the head of the Board of Control. These tempting offers, however, he declined, as inconsistent with those principles of liberty "which were then higher in his mind than twenty years before." But he was almost immediately returned on the Whig interest, as member for the county of Nairn. After this, his life scarcely admits of any detailed abstract. He continued in parliament, and true to liberal principles, for the remainder of his days. In 1818, he was appointed professor of law at Hayleybury, and resigned that situation in 1827. He had contemplated a similar appointment at Edinburgh, which, unhappily for the fame of the metropolitan university of Scotland, did not take place. He contributed articles of great value to the *Edinburgh Review;* and in a Preliminary Discourse to this work, being the second in order, furnished by far the best history of ethical philosophy that has ever been given to the world, and which has been reprinted in an octavo size, with a valuable preface by Professor Whewell of Cambridge. To Sir Samuel Romilly, in his exertions for the improvement of the criminal law, he gave the most efficient and zealous support; and, after the death of that virtuous lawyer, became the leader in that most necessary and unexceptionable branch of reform. After printing several volumes of a popular and abridged History of England, which contains more thought and more lessons of wisdom than any other history with which we are acquainted, he left, at his death, the invaluable fragment of the History of the Revolution of 1688, of which a very masterly account will be found in the sixty-second volume of the *Edinburgh Review.* Under Lord Grey's administration, in 1830, he was appointed to a seat at the Board of Control, and cordially co-operated in all the great measures of reform which were then brought forward, and carried after a severe struggle. He died in 1832, regretted with more sincerity, and admired with less envy, than any man of his age. In him, perhaps more than in any man of his time, was exemplified that *mitis sapientia,* which formed the distinguishing attribute of the illustrious friend of Cicero, and which wins its way into the heart, whilst it at once enlightens and satisfies the understanding.

With regard to the intellectual character of Sir James Mackintosh, we cannot do better than quote the words in which the able writer who reviewed the Memoirs of his Life by his son, in that journal to which he was so valuable a contributor, has described, or rather pourtrayed it. "His intellectual character cannot be unknown to any one acquainted with his works, or who has even read many pages of the Memoirs now before us; and it is needless, therefore, to speak here of his great knowledge, the singular union of ingenuity and soundness in his speculations—his perfect candour and temper in discussion—the pure and lofty morality to which he strove to elevate the minds of others, and in his own conduct to conform, or the wise and humane allowance which he was ready, in every case but his own, to make for the infirmities which must always draw down so many from the higher paths of their duty. These merits, we believe, will no longer be denied by any who have heard of his name or looked at his writings. But there were other traits of his intellect, which could only be known to those who were of his acquaintance, and which it is still desirable that the readers of these Memoirs should bear in mind. One of these was that ready and prodigious memory, by which all that he learned seemed to be at once engraved on the proper compartment of his mind, and to present itself at the moment it was required; another, still more remarkable, was the singular maturity and completeness of all his views and opinions, even upon the most abstruse and complicated questions, though raised, without design or preparation, in the casual course of conversation. In this way it happened that the sentiments he delivered had generally the air of recollections—and that few of those with whom he most associated in mature life could recollect of ever catching him in the act of making up his mind in the course of the discussions in which it was his delight to engage them. His conclusions, and the grounds of them, seemed always to have been previously considered and digested; and though he willingly developed his reasons, to secure the assent of his hearers, he uniformly seemed to have been perfectly ready, before the cause was called on, to have delivered the opinion of the court, with a full summary of the arguments and evidence on both sides. In the work before us, we have more peeps into the preparatory deliberations of his great intellect—that scrupulous estimate of the grounds of decision, and that jealous questioning of first impressions, which necessarily precede the formation of all firm and wise opinions,—than could probably be collected from the recollections of all those who had most familiar access to him in society. It was owing perhaps to this vigour and rapidity of intellectual digestion that, though all his life a great talker, there never was a man that talked half so much, who said so little that was either foolish or frivolous; nor any one perhaps who knew so well how to give as much liveliness and poignancy to the most just and even profound observations as others could ever impart to startling extravagance and ludicrous exaggeration. The vast extent of his information, and the natural gaiety of his temper, made him independent of such devices for producing effect, and, joined to the inherent kindness and gentleness of his disposition, made his conversation at once the most instructive and the most generally pleasing that could be imagined."

We cannot deny ourselves the satisfaction of adorning this meagre notice with another citation from the same admirable article, in which the writer replies to and exposes the depreciatory judgment of Mr Coleridge. The passage is severe, but not more so than the occasion and the aggression seemed to require. "In the *Table Talk* of the late Mr Coleridge, we find these words, 'I doubt if Mackintosh ever heartily appreciated an eminently original man. After all his fluency and brilliant erudition, you can rarely carry off anything worth preserving. You might not improperly write upon his forehead, Warehouse to let.' We wish to speak tenderly of a man of genius, and, we believe, of amiable dispositions, who has been so recently removed from his friends and admirers. But so portentous a misjudgment as this, and coming from such a quarter, cannot be passed over without notice. If Sir James Mackintosh had any talent more conspicuous and indisputable than another, it was that of appreciating the merits of eminent and original men. His great learning and singular soundness of judgment enabled him to do this truly; while his kindness of nature, his zeal for human happiness, and his perfect freedom from prejudice and vanity, prompted him, above most other men, to do it heartily. As a proof, we would merely refer our readers to his admirable character of Lord Bacon (*Edinburgh Review*, No. 53, vol. xxvii.). And then, as to his being a person from whose conversation little could be carried away, why, the most characteristic and remarkable thing about it was, that the whole of it might be carried away—it was so lucid, precise, and brilliantly perspicuous. The joke of the 'Warehouse to let' is not, we confess, quite level to our capacities. It can scarcely mean (though that is the most obvious sense) that the head was empty, as that is inconsistent with the rest even of this splenetic delineation. If it was intended to insinuate that it was ready for the indiscriminate reception of anything which any one might choose to put into it, there could not be a more gross misconception, as we have no doubt Mr Coleridge must often have sufficiently experienced. And by whom is this discovery, that Mackintosh's conversation presented nothing that could be carried away, thus confidently announced? Why, by the very individual against whose own oracular and interminable talk the same complaint has been made, by friends and by foes, and with an unanimity unprecedented, for the last forty years. The admiring, or rather idolizing, nephew, who has lately put forth this hopeful specimen of his relics, has recorded in the preface, that 'his conversation at all times required attention; and that the demand on the intellect of the hearer was often very great; and that when he got into his "huge circuit" and large illustrations, most people had lost him, and naturally enough supposed that he had lost himself.' Nay, speaking to this very point, of the ease or difficulty of carrying away any definite notions from what he said, the partial kinsman is pleased to inform us, that, with all his familiarity with the style of his relative, he himself has often gone away, after listening to him for several delightful hours, with divers masses of reasoning in his head, but without being able to perceive what connection they had with each other. 'In such cases,' he adds, 'I have mused, *sometimes even for days afterwards*, upon the words, till at length, spontaneously as it were, the fire would kindle,' &c. And this is the person who is pleased to denounce Sir James Mackintosh as an ordinary man; and especially to object to his conversation, that, though brilliant and fluent, there was rarely anything in it which could be carried away.

"An attack so unjust and so arrogant leads naturally to comparisons which it would be easy to follow out, to the signal discomfiture of the party attacking. But without going beyond what is thus forced upon our notice, we shall only say, that nothing could possibly set the work before us in so favourable a point of view as a comparison between it and the volumes of *Table Talk*, to which we have already made reference—unless, perhaps, it were the contrast of the two minds which are respectively pourtrayed in these publications.

"In these memorials of Sir James Mackintosh, we trace throughout, the workings of a powerful and unclouded intellect, nourished by wholesome learning, raised and instructed by fearless though reverent questionings of the sages of other times (which is the permitted necromancy of the wise), exercised by free discussion with the most distinguished among the living, and made acquainted with its own strength and weakness, not only by a constant intercourse with other powerful minds, but by mixing, with energy and deliberation, in practical business and affairs; and here pouring itself out in a delightful miscellany of elegant criticism, original speculation, and profound practical suggestions on politics, religion, history, and all the greater and the lesser duties, the arts and the elegancies of life—all expressed with a beautiful clearness and tempered dignity—breathing the purest spirit of goodwill to mankind—and brightened not merely by an ardent hope, but an assured faith in their constant advancement in freedom, intelligence, and virtue.

"On all these points, the *Table Talk* of his poetical contemporary appears to us to present a most mortifying contrast; and to render back merely the image of a moody mind, incapable of mastering its own imaginings, and constantly seduced by them, or by a misdirected ambition, to attempt impracticable things—naturally attracted by dim paradoxes rather than lucid truth, and preferring, for the most part, the obscure and neglected parts of learning to those that are useful and clear—marching, in short, at all times, under the exclusive guidance of the Pillar of Smoke—and, like the body of its original followers, wandering all his days in the desert, without ever coming in sight of the promised land." (A.)

MACKLAHSUL, a town of Hindustan, in the province of Berar, and district of Gaungra, on the north side of the Tuptee river, 20 miles north-east from Gawelghur. Long. 77. 34. E. Lat. 21. 64. N.

MACKOOR, a district of Hindustan, in the province of Berar, extending along the river Kaitna, and situated between the 20th and 21st degrees of north latitude. The principal towns are Omerpoor, Shahpoor, and Jaffierabad.

MACKWA, a town of Hindustan, in the Northern Circars, 40 miles west-north-west from Cicacole. Long. 83. 24. E. Lat. 18. 33. N.

MACLAURIN, Colin, a very eminent mathematician and philosopher, was the son of a clergyman, and born at Kilmoddan, Scotland, in 1698. In the year 1709 he was sent to the university of Glasgow, where he continued five years, and applied himself intensely to study. His great genius for mathematical learning discovered itself as early as the age of twelve, when, having accidentally met with an Euclid in a friend's chamber, he became in a few days master of the first six books without any assistance; and it is certain, that in his sixteenth year he had invented many of the propositions which were afterwards published under the title of *Geometria Organica.* In his fifteenth year he took the degree of master of arts, and on that occasion composed and publicly defended, with great applause, a thesis on the power of gravity. After this he quitted the university, and retired to a country-seat of his uncle, who had the care of his education; for his parents had been some time dead. Here he spent two or three years in pursuing his favourite studies; but, in 1717, he offered himself as a candidate for the professorship of mathematics in the Marischal College of Aberdeen, and obtained it after a ten days' trial with a very able competitor. In 1719 he went to London, where he became acquainted with Dr Hoadly, then bishop of Bangor, Dr Clarke, Sir Isaac Newton, and other eminent men, at which time also he was admitted a member of the Royal Society; and in another journey in 1721, he contracted an intimacy with Martin Folkes, the president of the society, which continued until his death.

In 1722, Lord Polwarth, plenipotentiary of the king of Great Britain at the congress of Cambray, engaged him to become tutor and companion to his eldest son, who was then about to set out on his travels. After a short stay at Paris, and visiting other towns in France, they fixed in Lorraine, where Maclaurin wrote his tract on the percussion of bodies, which gained the prize of the Royal Academy of Sciences for the year 1724. But his pupil dying soon afterwards, at Montpellier, he returned immediately to his profession at Aberdeen. He was hardly settled there, however, when he received an invitation to Edinburgh; the curators of that university being desirous that he should supply the place of Mr James Gregory, whose great age and infirmities had rendered him incapable of teaching. He had some difficulties to encounter, arising from competitors, who had good interest with the patrons of the university, and also from the want of an additional fund for the new professor; but at length these were all surmounted, principally by the means of Sir Isaac Newton. In November 1725 he was introduced into the university. After this, the mathematical classes soon became very numerous, there being generally upwards of a hundred young gentlemen attending his lectures every year, who being of different standing and proficiency, he was obliged to divide them into four or five classes, in each of which he employed a full hour every day, from the first of November till the first of June.

He lived a bachelor till the year 1733; but being not less formed for society than for contemplation, he then married Anne, the daughter of Mr Walter Stewart, solicitor-general for Scotland. By this lady he had seven children, of whom two sons and three daughters, together with his wife, survived him. In 1734, Berkeley, bishop of Cloyne, published a piece called *The Analyst,* in which he took occasion, from some disputes which had arisen concerning the grounds of the method of fluxions, to attack the method itself, and also to charge mathematicians in general with infidelity in religion. Maclaurin thinking himself included in this charge, began an answer to Berkeley's book; but, as he proceeded, so many new theories and problems occurred to him, that instead of a vindicatory pamphlet, his work came out a complete system of Fluxions, with their application to the most considerable problems in geometry and natural philosophy. This work was published at Edinburgh in 1742, in two vols. quarto; and as it cost him infinite pains, so it is the most considerable of all his works. In the mean time, he was continually obliging the public with some performance or observation of his own, many of which were published in the fifth and sixth volumes of the Medical Essays at Edinburgh. Some of them were likewise published in the Philosophical Transactions, particularly, 1. Of the Construction and Measure of Curves; 2. A new Method of describing all kinds of Curves; 3. A Letter to Martin Folkes, Esq. on Equations with impossible Roots, May 1726; 4. Continuation of the same, March 1729; 5. On the Description of Curves, with an account of farther improvements, and a paper dated at Nancy, November 27, 1722; 6. An account of the Treatise of Fluxions, January 27, 1742; 7. The same continued, 10th March 1742; 8. A Rule for finding the meridional parts of a Spheroid with the same exactness as of a Sphere, August 1741; 9. Of the basis of the cells wherein the Bees deposit their Honey, 3d November 1734.

In the midst of these studies, he was always ready to lend his assistance in contriving and promoting any scheme that might contribute to the service of his country. When the Earl of Morton set out in 1739 for Orkney and Zetland, to visit his estates there, he desired Mr Maclaurin to assist him in settling the geography of those countries, which is very erroneous in all our maps; to examine their natural history, survey the coasts, and measure a degree of the meridian. Maclaurin's family affairs, and other connections, would not permit him to do this; he, however, drew up a memorial of what he thought necessary to be observed, furnished the proper instruments, and recommended Mr Short the optician as a fit person for the management of them. He had still another scheme for the improvement of geography and navigation, of a more extensive nature; which was the opening of a passage from Greenland to the South Sea by the north pole. That such a passage might be found, he was so fully persuaded, that he has been heard to say, that if his situation admitted of such adventures, he would undertake the voyage, even at his own charge. But when schemes for discovering it were laid before the parliament in 1744, and he was himself consulted by several persons of high rank concerning them, before he could finish the memorials which he proposed to send, the premium was limited to the discovery of a north-west passage; and he used to regret that the word west was inserted, because he conceived that the passage, if it existed at all, would be found not far from the pole.

In 1745, having been very active in fortifying the city of Edinburgh against the Highland army, he was obliged to fly from thence to the north of England, where he was invited by Herring, then archbishop of York, to reside with him during his stay in this country. In this expedition, however, being exposed to cold and hardships, and naturally of a weak and delicate constitution, he laid the foundation of an illness which put an end to his life, in June 1746, at the age of forty-eight.

Mr Maclaurin was a good as well as a great man, and worthy of esteem as well as admiration. His peculiar merit as a philosopher consisted in this, that all his studies were accommodated to general utility; and we find, in many places of his works, an application even of the most abstruse theories, to the perfecting of the mechanical arts. For this purpose, he had resolved to compose a course of practical mathematics, and to rescue several useful branches of the science from the bad treatment which they had often met with in less skilful hands. But all this was prevented by his death; unless we should reckon, as part of his intended work, the translation of Dr David Gregory's *Practical Geometry*, which he revised, and published with additions in 1745. In his lifetime, however, he had frequent opportunities of serving his friends and his country by his great skill. Whatever difficulty occurred concerning the constructing or perfecting of machines, the working of mines, the improving of manufactures, the conveying of water, or the execution of any other public work, he was at hand to resolve it. He was likewise employed to terminate some disputes of consequence which had arisen at Glasgow concerning the gauging of vessels; and for that purpose presented to the Commissioners of Excise two elaborate memorials, with demonstrations, containing rules by which the officers now act. He also made calculations relating to the provision, now established by law, for the widows and children of the Scotch clergy, and of the professors in the universities, entitling them to certain annuities and sums, upon the voluntary annual payment of a certain sum by the incumbents. In contriving and adjusting this wise and useful scheme he bestowed a great deal of labour, and contributed not a little towards bringing it to perfection. Of such a man, it may be said that he lived to some purpose; which can hardly be predicated of those, how uncommon soever their abilities and attainments, who spend their whole time in abstract speculations, and produce nothing really useful or serviceable to their fellow-creatures.

Of his works, we have mentioned his *Geometria Organica*, in which he treats of the description of curve lines by continued motion. We need not repeat what has been said concerning the paper which gained the prize of the Royal Academy of Sciences in 1724. In 1740 the academy adjudged him a prize, which did him still more honour, for solving the motion of the tides from the theory of gravity; a question which had been given out the previous year, but without receiving any solution. He had only ten days to draw up this paper, and could not find leisure to transcribe a fair copy; so that the Paris edition of it is incorrect. He afterwards revised the whole, and inserted it in his Treatise of Fluxions; as he did also the substance of the former paper. These, with the Treatise of Fluxions, and the pieces printed in the Philosophical Transactions, of which we have given a list, are all the writings which Maclaurin lived to publish. Since his death, two more volumes have appeared, containing his Algebra, and his Account of Sir Isaac Newton's Philosophical Discoveries. His Algebra, though not finished by himself, is yet allowed to be excellent of its kind, containing, in a volume of no great bulk, a complete elementary treatise of that science, as far as it had then been carried. The occasion of his Account of Sir Isaac Newton's Philosophy may be shortly stated. Sir Isaac having died in the beginning of 1728, his nephew, Mr Conduitt, proposed to publish an account of his life, and desired Mr Maclaurin's assistance. The latter, out of gratitude to his great benefactor, cheerfully undertook, and soon finished, the history of the progress which philosophy had made before Sir Isaac's time; and this was the first draught of the proposed work; but as the latter did not go forward, on account of Mr Conduitt's death, the manuscript was returned to Mr Maclaurin. To this he afterwards made great additions, and left it in the state in which it now appears. See the DISSERTATIONS prefixed to this work.

MACON, an arrondissement of the department of the Saone and the Loire, in France, extending over 454 square miles. It is divided into nine cantons, and subdivided into 135 communes, containing 108,500 inhabitants. The capital is the city of the same name, and it is also the capital of the department. It is situated on the right bank of the Saone, over which is a fine bridge. It is ill built, with narrow, crooked streets; and the only fine object is the quay by the side of the river, the Hôtel de Ville, and the palace Montrevel. It contains 1400 houses, with 10,000 inhabitants, whose chief trade is in wine, and in linen and stocking weaving. Long. 4. 44. 48. E. Lat. 46. 18. 17. N.

MACOWALL, a Sikh town in the province of Lahore, on the banks of the Sutleje river, 133 miles from the city of Lahore. Long. 75. 38. E. Lat. 31. 14. N.

MACQUARRIE ISLAND, in the South Pacific Ocean, was discovered in 1811, by some resolute adventurers from New Holland, who had penetrated into the Southern Ocean in prosecution of the seal fishery. It is eighteen miles in length from north to south, and about six in breadth. At the distance of eight leagues from the north point of this island are other smaller islands, called the Judge and his Clerks, and several others in a south direction, called the Bishop and his Clerks. Long. 169. E. Lat. 52. 41. S.

MACQUER, PIERRE JOSEPH, was born at Paris on the 9th of October 1718, and died there on the 16th of February 1784. He was member of the Academy of Sciences, and professor of pharmacy; and was engaged in the *Journal de Sçavans* for articles in medicine and chemistry. With the last of these sciences he was intimately acquainted. He had a share in compiling the *Pharmacopœia Parisiensis*, published in 1758, in 4to. His other works are, 1. Elémens de Chimie Théorique, Paris, 1749, 1753, 12mo; 2. Elémens de Chimie Pratique, 1751, in two vols. 12mo; 3. Plan d'un cours de Chimie Expérimentale et Raisonnée, 1757, 12mo, in the composition of which he was associated with M. Beaumé; 4. Formulæ Medicamentorum Magistralium, 1763; 5. L'Art de la Teinture en Soie, 1763; 6. Dictionnairc de Chimie, contenant la Théorie et la Pratique de cet Art, 1766, in two vols. 8vo, which has been translated into German with notes, and into English with notes by Mr Keir. Macquer has, by his labours and writings, greatly contributed to render useful an art which formerly tended only to ruin the health of the patient by foreign remedies, or to reduce the professors of it to beggary, whilst they prosecuted the idle dream of converting every thing into gold.

M‘CRIE, THOMAS, D.D., an eminent biographer and divine, was born at Dunse, in North Britain, in the month of November 1772. His parents belonged to the class of Seceders known in Scotland as Antiburghers, and he was educated with a view to the ministry in that persuasion. After passing through the ordinary course of education afforded in a country town, he came to Edinburgh, and enrolled himself as a student in the university, in the winter of 1788.[1] During that and the two following sessions he pursued the course of literary and philosophical study prescribed to students intending to devote themselves to the ministry; and in 1791, he entered the theological class at Whitburn, under the Rev. Archibald Bruce, the teacher or professor of divinity to the Associate Antiburgher Synod. As the attendance upon this course was only for a limited period each year, it was usual for the students, whose means were generally very scanty, to employ the intervals in teaching. In this way Mr M‘Crie, in the autumn of 1791, proceeded to Brechin, and opened a school in connection with the Associate Antiburgher congregation in that town; and he continued there, excepting the time annually required at Whitburn in the three following sessions (1792 to 1794) for completing the regular course of theological study.

Towards the end of 1795, Mr M‘Crie was licensed to preach by the presbytery of Kelso. In the beginning of the next year, he received a call from the Second associate congregation of Antiburghers in Edinburgh; and some scruples having been obviated by an act of the Associate

[1] Matriculation books of the University.—At this time he wrote his name M^{c}Crie; and in strict arrangement this article belonged to a former sheet.

Synod, dated 3d May 1796, he was ordained to that charge on the 26th of that month.[1] In this pastoral relationship he continued for upwards of ten years, evidently with the sincere attachment of his people.

At this period, Mr M‘Crie, by diligent and assiduous study, was acquiring that profound theological knowledge, and that fund of literary and ecclesiastical information, for which, in after life, he was so distinguished. The proceedings of the religious body with whom he was connected may also have had some effect in directing his pursuits towards subjects connected with the history, constitution, and polity of the reformed church. Yet, excepting a missionary sermon, which was published in 1797, at the special request of his congregation,[2] we cannot trace back the commencement of his literary career farther than the year 1803, although some articles, of an earlier date, in a periodical work entitled " The Christian Magazine, or Evangelical Repository," may have proceeded from his pen.[3] To this magazine he contributed a series of articles, with the signature of PHILISTOR (a lover of history), and these included, in 1803, " The History of the New Testament confirmed and illustrated by passages of Josephus, the Jewish historian;" " Memoir of Mr John Murray, minister of Dunfermline ; " Sketch of the Progress of the Reformation in Spain, with an account of Spanish Protestant Martyrs ;" and " Illustrations of Scripture as to the grinding and parching of Corn." In 1804, " Suppression of the Reformation in Spain, with a continuation of the Account of Spanish Protestant Martyrs ;" " Remarks on Matthew, xx. 25, 26 ;" " On the Origin of the Taborites ;" " Life of John Wickliffe ;" " Life of John Huss ;" " Martyrdom of Jerome of Prague ;" " Martyrs in Britain, from the time of Wickliffe to the Reformation ;" and " Influence of the Opinions of Wickliffe upon the English Reformation, with additional notices of Martyrs." In 1805, " The Life of Theodore Beza ;" and the " Life of Dr Andrew Rivet," a Protestant divine in France. In 1806, " The Life of Patrick Hamilton, the Proto-Martyr of the Reformation in Scotland ;" " The Life of Francis Lambert of Avignon ;" " Account of Bugenhagen, a German Reformer ;" " The Life of Alexander Henderson, minister of Edinburgh, and one of the commissioners from the Church of Scotland to the Assembly of Divines at Westminster ;" and " Historical Notices respecting learned Scottish Divines in England and Foreign Parts, during the sixteenth century."

We have been particular in enumerating the titles of the above articles, as they show very distinctly the peculiar bent of Mr M‘Crie's mind, at this early period, towards subjects illustrative of the history and progress of the Reformation throughout Europe, and of the biography of eminent martyrs and reformers ; in fact, containing the germs of most of his subsequent publications.

We have now arrived at a point in Mr M‘Crie's history, which makes it necessary to advert to the proceedings of the Associate Synod. But to enter into such minute details as might render the subject sufficiently intelligible to a general reader, would not only occupy too much space, but might seem to be misplaced in this work. Yet it would be false delicacy, even in a sketch of his literary life like the present, to pass in silence the results of such proceedings ; and the more so, as his conduct, in the painful situation in which he was placed, displayed no small degree of Christian resignation and fortitude, and evinced that he was sustained by a sense of duty and high-minded principle. Suffice it then to say, that Mr M‘Crie was one of five ministers[4] who felt themselves constrained to resist and protest against what they considered to be a spirit of innovation on the part of the Synod, while engaged in the revisal and enlargement of the Judicial Act and Testimony, which had hitherto served as the bond of ministerial and religious communion, in order, as it was expressed, to adapt it " more to the circumstances of the present time." It need only be stated, that the chief points of difference related to the apparent abandonment by the Synod of some important principles of the Judicial Act and Testimony,—more especially the received doctrine on the connection between church and state, the power of the civil magistrate in matters of religion, and the lawfulness and perpetual obligation of our national covenants,—points which had hitherto been maintained by the members of Secession. In this revisal the Synod continued at their half-yearly meetings, until it was completed in April 1804, and published under the title of " Narrative and Testimony agreed upon and enacted by the General Associate Synod," &c. This contained, first, " A Narrative of the State of Religion in Britain and Ireland, from the period of the Reformation to the present time," including a history of the Secession Church, and a view " Of the progressive Defections of the Established Church of Scotland ;" and, secondly, the Testimony, or Declaration, under several heads, of the doctrinal sentiments professed by the Associate Synod, along with a Formula, which should hereafter be " the term of admission for those who shall apply for joining in communion with us."

The case of the four surviving protestors who had disclaimed the power of the Associate Synod, either to alter their original Testimony, or to impose new terms of communion for their body, was before the meeting of the Synod at Glasgow, at the end of August 1806, and, by a formal resolution, was postponed till the ensuing meeting in April next. It happened, however, that whilst the subject was under discussion, Mr M‘Crie and other two of the protestors met at Whitburn to assist Mr Bruce upon a sacramental occasion ; and these four, after serious deliberation, constituted themselves into a separate presbytery or jurisdiction. Information of this having reached Edinburgh, Mr M‘Crie was interrogated by some members of his session, when he admitted the fact; immediately upon which a communication was transmitted to the Synod at Glasgow; and as it was considered that, "with regard to Mr M'Crie, forbearance could no longer be tolerated," it was moved, and a sentence passed (2d of September), deposing him from the office of the holy ministry.[1] The other protesting ministers were afterwards deposed in as peremptory a manner. It may be said that the Synod could not act otherwise in regard to their brethren who had set themselves in such direct opposition, by disclaiming the jurisdiction of that court. But, to say nothing of the precipitate manner of passing such a sentence, it was at least a harsh, if not unjustifiable proceeding, to subject to the summary punishment of deposition and excommunication, persons against whom calumny had never surmised the slightest charge, either as to moral conduct or error in doctrine; and while, by so doing, dissensions were raised in congregations, it was somewhat strange to find the very men who repudiated the doctrine of interference of the civil magistrate in matters of religion, calling in such aid to exclude from their own congregations ministers who had been regularly ordained, and who maintained all the obligations imposed upon them at ordination. Yet all this was done, according to Mr Bruce's statement, "under high pretensions to lenity and moderation, of promoting universal liberty of conscience, and of greatly detesting and condemning all impositions and compulsion;" and, as he elsewhere remarks, that "to dissolve a pastoral relation duly established, and while mutually acknowledged, by mere church authority, without relevant reasons, is as really oppression, and a robbing the people of their sacred privileges, as to intrude a minister upon a congregation without their consent, which was one of the chief and primary grounds of the Secession."[2]

---

[1] This congregation was constituted in 1791, and their meeting-house in the Potterrow was erected in 1792 ; but they enjoyed the advantage of a settled minister only when Mr M‘Crie was ordained. The sermon and address at his ordination, 26th May 1796, form part of a volume (pp. 164–202) of " Sermons preached on different occasions, by Robert Chalmers, minister of the Gospel at Haddington." Edinburgh, 1798, 12mo, pp. 440.

[2] " The Duty of Christian Societies towards each other, in relation to the measures for propagating the Gospel which at present engage the attention of the Religious World. A Sermon, preached in the Meeting-house, Potterrow, on occasion of a collection for promoting a Mission to Kentucky." Edinburgh, 1797, 8vo, pp. 40. This sermon Mr M‘Crie afterwards had some wish to suppress, at least he regretted its publication, from having changed his views on some points which it embraced.

[3] This periodical work, in sixpenny numbers, was commenced in February 1797. In the number for April 1801 is a " Proposed Plan of a New Literary Society, to be named The Voluntary Society for Improvement in Ecclesiastical History and Biography ;" and in September 1802, a translation of part of Smeton's Life and Death of John Knox, from the Latin, 1579, both of which probably were contributions from Mr M‘Crie. One of the editors, the Reverend George Whytock, Dalkeith, having died about the end of 1805, Mr M‘Crie became the sole editor of the volume for 1806 ; but a variety of circumstances led to its discontinuance, and a new series was commenced in January 1807, chiefly under the auspices of his brethren from whom he had separated, as stated above.

[4] The other members were, the Rev. Archibald Bruce, Whitburn ; Rev. George Whytock, Dalkeith ; Rev. James Aitken, Kirrymuir ; and the Rev. James Hog, Kelso. Mr Whytock died in October 1805, nearly twelve months before the Synod proceeded to extremities. The other protestors were afterwards joined by the Rev. Robert Chalmers, Haddington.

The Synod having appointed one of their number to proceed to Edinburgh, to intimate, on the next Sabbath (7th September), the sentence of Mr M'Crie's deposition, from his own pulpit, we must next briefly advert to the proceedings of his congregation. It appears that the leaven of the new-light doctrines had lately infected several of the leading members; yet, as it was found that the trustees and seat-holders, both in point of number, and the amount paid for sittings, were nearly equal, the question arose, to whom the property of the meeting-house in the Potterrow belonged. Such disunion was the occasion of a tedious litigation in the Court of Session, during which time he was interdicted access to his pulpit on the afternoon of every Sabbath. The Court of Session having declined entering upon the question as to which party was chargeable with schism, at length pronounced a decision, 24th February 1809, in favour of the new-light members, as "forming a congregation of Christians in communion with, and subject to the ecclesiastical discipline of, a body of dissenting Protestants, calling themselves the Associate Presbytery and General Associate Synod of Antiburgher Seceders."[3] After this, Mr M'Crie's congregation assembled in the meeting-house in Carrubber's Close, till their new chapel in Davie Street, Richmond Place, was erected, and in which he continued to officiate till the close of his life.

In the meanwhile, the small party of "Old-Light Antiburghers," as the protestors were commonly called, assumed the name of the "Constitutional Associate Presbytery;" and, finding themselves placed in such peculiar circumstances, and their sentiments and conduct liable to misrepresentation, they resolved to publish "a fuller statement and explanation of the principal heads of controversy between the Synod and them." For this purpose, the task was devolved upon Mr M'Crie, as clerk of the presbytery; and, from papers partly written and wholly revised by him, there appeared, in 1807, under his name, a "Statement of the Difference between the profession of the Reformed Church of Scotland, as adopted by Seceders, and the profession contained in the New Testimony and other Acts, lately adopted by the General Associate Synod; particularly on the power of Civil Magistrates respecting Religion, National Reformation, National Churches, and National Covenants. To which are added, Reasons by the Ministers who Protested against the above Acts of Synod, for constituting themselves into a separate Presbytery, with the deed of Constitution," &c. 8vo, pp. 234. Although of a controversial nature, respecting differences which attracted no very great share of public notice at the time, this Statement is also applicable to discussions which have recently been much more widely agitated by the voluntary question; and it may be appealed to by the friends of the established church, as explaining and enforcing the true grounds of connection between the church and state, and as an able and elaborate argument of the obligation on civil rulers to make suitable provision for the religious interests of the community. Yet it was generally conceived that the protestors had displayed unnecessary zeal and obstinacy in stedfastly opposing the measures of the Synod, as if they had been contending for mere abstract theoretical points of no practical importance.

In the comparatively obscure and humble situation in which Mr M'Crie was now placed, he was enabled to devote his leisure hours to his favourite literary pursuits. His intention was to have published a life of Alexander Henderson, the eminent Scottish divine, of which a sketch had appeared in the Christian Magazine. In the view of giving an introductory account of the state of the reformed church, he found that the materials were amply sufficient for a separate work; and abandoning his original design, as one that might be resumed at some future time, he undertook a Life of John Knox, and in this form sought to illustrate the earlier history of the Protestant church in Scotland. The subject was felicitously chosen, not only as possessed of historical importance and of national interest, but as one which required, and which was capable of being placed in a new point of light. "The Life of John Knox, containing Illustrations of the History of the reformation in Scotland," appeared in the beginning of 1812, in one volume 8vo, pp. 580. Such was the effect produced by this work, that although, even in Edinburgh, the author's name was quite unknown in the literary circles, it placed him at once in the first rank of ecclesiastical biographers, and established his reputation as an historical writer, both at home and abroad. The character of the great reformer had hitherto been much calumniated and mistaken. Knox, indeed, was one of the most marked characters in Scottish history, admirably suited to the circumstances in which he was placed. He had, however, been too often represented as a fierce and sullen bigot, equally opposed to learning, liberal principles, and sound policy; coarse in manners, intolerant in conduct, and actuated by sordid and ambitious views. It remained to reverse the picture, and to show the reformer in a juster light; influenced by the purest and noblest principles; filled with apostolical zeal, and a total disregard of worldly rank and power; stern and uncompromising only in the cause of truth, and in reproving vice and error; distinguished for profound learning and true piety; and with that incorruptible integrity and heroic courage required for carrying on the work of reformation. All this was accomplished in Mr M'Crie's work, which possessed the rare quality of uniting history with biography; and it was noticed in terms of high commendation in most of the leading journals of the time. As, in fact, the "Life of Knox" must be held to be the author's principal production, we cannot resist the opportunity of giving a quotation from an article in the Edinburgh Review for July 1812, usually ascribed to the distinguished editor.

[1] See "Letters on the late Transactions of the General Associate Synod at Glasgow," in the New Series of the *Christian Magazine*, vol. i. pp. 24-35, 61-72. The anonymous writer of these Letters asserts that the Protestors had all along been treated by the Synod with great lenity and forbearance.

[2] "A Review of the Proceedings of the General Associate Synod, and of some Presbyteries, in reference to the Ministers who protested against the imposition of a New Testimony," &c.; by A. Bruce, minister in Whitburn, p. 405. Edinburgh, 1808, 8vo.

[3] Faculty Decisions, 1808-1809, p. 221.

"How unfair, and how marvellously incorrect, these representations (of Knox's character) are, may be learned from the book before us; a work which has afforded us more amusement and more instruction than any thing we ever read upon the subject; *and which*, independent of its theological merits, *we do not hesitate to pronounce by far the best piece of history which has appeared since the commencement of our critical career.* It is extremely accurate, learned, and concise, and at the same time very full of spirit and animation; exhibiting, as it appears to us, a rare union of the patient research and sober judgment which characterise the more laborious class of historians, with the boldness of thinking, and force of imagination, which is sometimes substituted in their place. It affords us very great pleasure to bear this public testimony to the merits of a writer who has been hitherto unknown, we believe, to the literary world, either of this or the neighbouring country; of whom, or of whose existence at least, though residing in the same city with ourselves, it never was our fortune to have heard till his volume was put into our hands; and who, in his first emergence from the humble obscurity in which he has pursued the studies and performed the duties of his profession, has presented the world with a work which may put so many of his contemporaries to the blush, for the big promises they have broken, and the vast opportunities they have neglected."

Such a favourable award had the effect of directing attention to the work, and of calling for a new edition, which appeared in an enlarged and corrected form in 1813.[1] In preparing this edition, the author not only made corrections, both as to style and matter, but, as the reformer's name is so inseparably connected with the history of public events, he introduced greater detail of public transactions, tending to vindicate the proceedings of the early reformers, and to throw light on the character and motives of the other prominent actors of the time.

Before this edition was published, the Senatus of the University of Edinburgh, on the 3d of February 1813, conferred on Mr M'Crie the honorary degree of Doctor of Divinity; a compliment alike deserved by the author of the Life of Knox, and honourable to his Alma Mater, our metropolitan university. This act was the more honourable, as it was one of the first instances of such a title having been conferred on a person, though holding the same professions, not strictly belonging to the established church.

Thus encouraged to pursue his literary career, the next subject in which Dr M'Crie engaged was a Life of Andrew Melville, the able and intrepid assertor of Presbytery; which might serve as a continuation to his former work, by giving an account of ecclesiastical transactions in Scotland during the latter part of the sixteenth and beginning of the seventeenth century. It was not till the end of 1819 that the work was published, in two volumes 8vo.[2] It presented the results of long-continued, minute, and discriminating research into the literary as well as the ecclesiastical history of the period. The exertions of Melville in behalf of our national church well merited the labours of such a biographer; and as he was successively at the head of two of our principal colleges, Glasgow and St Andrews, an opportunity was also afforded of entering fully into the state of education and the progress of literature at that time. Although in no respect less valuable and important, it was not so successful as its precursor; as, in fact, the mass of literary information it conveys was not of a kind to attract public regard and secure popularity. Melville's influence in church courts far surpassed that of any of his contemporaries, but it was not so powerfully felt, like that of Knox, in public events. Yet his character is highly interesting, and stands out in bold relief, finely contrasted with the milder dispositions of his nephew James Melville (whose Diary presents so many minute and affectionate notices of his uncle, whilst his own letters, written in exile, breathe a kindred spirit of sympathy and love), as an elegant and accomplished scholar, a profound divine, kind and affectionate in all the private relations of life, and at the same time undaunted and uncompromising in asserting and vindicating the rights and liberties of the presbyterian party. The period to which Dr M'Crie's work relates is not less important, as it embraces the contests between the church and the court, the establishment on its present basis of the presbyterian polity, and its temporary overthrow after a long and arduous struggle.

Having in the life of Melville traced the progress of ecclesiastical affairs till near the close of the reign of James I., it was natural to think that Dr M'Crie would have resumed his first intention, by publishing a Life of Alexander Henderson. But the state of his health, and the fear of engaging in such laborious and protracted researches as he had just terminated, deterred him from commencing, or at least induced him to postpone, such a task. Strong inducements, moreover, were held out to him, first to become the editor of a new edition of Wodrow's History, and afterwards to write a new work on the same period, or a history of the religious persecutions in Scotland; but neither of these was undertaken, and he remained for a length of time undetermined in what work he should next engage. Besides Henderson's life, he thought of Wickliffe and the precursors of Luther,—of Calvin,—and of a history of the progress of the Reformation throughout Europe. Various obstacles intervened to his successfully embarking in either of these undertakings, and therefore it is the more deeply to be regretted that any circumstances should have prevented him from pursuing his primary intention, which might for a time have happily limited his researches to his own country, and to events with which he was so conversant. We happen to know, that when Dr M'Crie was urged to this, all his old predilections would revive, and he would admit his anxious desire to continue the period of his biographies to the Restoration. He would say, however, that a life of Henderson, who died in 1646, would leave such a work incomplete, and he should feel some difficulty in fixing on any person of sufficient importance, and whose principles and conduct he approved, to connect with Henderson for the subsequent events. As his own views led him to approve of the party named "Protestors," he no doubt would, had he actually set about such a work, have given the preference to James Guthrie, minister of Stirling, who suffered as a martyr for his principles upon the restoration of Charles II. Besides the advantage of thus presenting, in the form of biographical narrative, a continuous history of what has been called the Second, as well as of the First Reformation, it was a subject calculated to excite very general interest; and the whole tenor of Dr M‘Crie's pursuits eminently fitted him to render it attractive. But it was destined to be left to other hands.[1] We have only to express a wish, that in the publication of his miscellaneous writings, which have been announced, a conspicuous place may be assigned to his admirable sketch of Henderson's life, which appeared in the Christian Magazine for 1806.

---

[1] The fifth edition, carefully revised by the author, and containing his last corrections, was published in 1831. This, as well as the second, third, and fourth editions, is in two volumes 8vo.

[2] The title is, "The Life of Andrew Melville; containing Illustrations of the Ecclesiastical and Literary History of Scotland during the latter part of the Sixteenth and beginning of the Seventeenth Century. With an Appendix, consisting of original papers." A second edition, revised, was published in 1824, also in 2 vols. 8vo.

Whilst engaged in the life of Melville, Dr M‘Crie became an occasional, if not a stated contributor, to the "Edinburgh Christian Instructor," a well-known monthly publication, edited by the late Reverend Dr Andrew Thomson, with whom he continued on terms of cordial intimacy and friendship till the close of his highly useful career. He also lent occasional aid to other periodicals; but as we have no means of exactly ascertaining his communications,[2] we shall merely allude to one article in the Instructor which excited considerable attention at the time. This was a review, in 1817, of the first series of the "Tales of my Landlord," which appeared in three successive numbers of that magazine, and contained an elaborate defence of the persecuted covenanters, who made such a noble struggle for civil as well as religious freedom, against the unprincipled and tyrannical measures of the government of Charles II., whilst it exposed the erroneous and exaggerated representation of their manners and principles given in the tale of "Old Mortality." But the most singular circumstance connected with this review was, that Sir Walter Scott, who had not then stood forth as the acknowledged author of the Waverley Novels, was prevailed upon, by the editor of the "Quarterly Review," to become the reviewer of his own work; and thus he took an opportunity, whilst vindicating the statements contained in his novel, tacitly to answer the article in the Instructor.

In February 1816, the Reverend Archibald Bruce, Antiburgher minister at Whitburn, who for upwards of thirty years had filled the office of professor of divinity, died full of years and honour, and Dr M‘Crie was naturally looked to as the fittest person in their body for his successor. The number of students was not considerable; but the duties of the professorship must have occupied much of his time during the ordinary terms of session. He commenced his lectures on the 1st of October 1817, with a suitable and feeling allusion to the loss the church at large had sustained by the death of his venerable friend and instructor. Two letters, written at the time of the funeral to a brother clergyman in the country, which have recently appeared,[3] bear strong testimony of his esteem and reverence for the worth and talents of this learned and worthy divine, who was distinguished by a congeniality of mind and fondness of literary research. Dr M‘Crie filled the professor's chair until 1827, when he resigned it in consequence of an event which may be adverted to in a few words. In 1820, a union of the two largest bodies of dissenters in Scotland took place, under the title of the "United Associate Synod of the Secession Church." Several members of the Antiburgher Synod having protested against the basis of union, and declined participating in it, formed themselves into a separate court, still retaining the name of the "Associate (Antiburgher) Synod." From their similarity of sentiment and profession with the "Constitutional Associate Presbytery," a proposal for re-uniting was afterwards brought forward, when Dr M‘Crie on the one side, and Professor Paxton on the other, were appointed to draw up the "Articles agreed upon, &c. with a view to Union," and the "Overtures of a Testimony." This union was effected in May 1827, under the designation of the "Associate Synod of Original Seceders;" and it was on this occasion that Dr M‘Crie resigned the divinity chair to the Rev. George (now Dr) Paxton, the learned author of "Illustrations of the Holy Scriptures." The "Testimony" then published, as agreed upon by the Synod, it is understood was the composition, in the historical part, of Dr M‘Crie, and in the doctrinal part, of Dr Stevenson, Ayr. Here it may be remarked, that the Church of Scotland owes no ordinary debt of gratitude to the Original Seceders, for their constant adherence to the same principles, and even for their continued testimony against error in the administration of church affairs. As to Dr M‘Crie individually, although he saw no prospect of being able conscientiously to join the establishment, he was ever warmly attached to the church, and felt a deep interest in her prosperity. Such attachment is manifested in all his writings, and remained unimpaired till the day of his death. A few words on this head may be quoted from a sermon on the aspect of the times, delivered in May 1834. Addressing the members of his own congregation, he says, "After long examination, I am fully convinced that, by the good hand of God, you have been led, in respect of profession and communion, to take up your ground in the safe medium between the conflicting parties in the great controversy of the day, while you continue to testify against the corruptions of the churches established by law in our native land, and at the same time keep aloof from those who condemn all recognition of Christianity by public authority, and seek to withdraw the provision which has been made by the nation for religious purposes. I cannot (he adds) flatter you with the prospect of the speedy removal of those defects in the national settlement of religion, or those practical abuses in ecclesiastical administration, which the body we are connected with have so long condemned, and which have excluded us from fellowship with the national church in Scotland...Nothing on earth would give more joy to my heart, than to see sure and decided symptoms of reformation in the national church of Scotland...I would go seven times to the top of her highest mountain to look out for the harbinger of her relief, though each time I should have to return with the message, 'There is nothing,' provided at last I could hail the appearance of 'the little cloud out of the sea, like a man's hand,' the sure prelude of the plentiful rain which shall refresh the weary inheritance, make her wilderness an Eden, and her desert as the garden of the Lord."

But, to resume the series of Dr M‘Crie's literary labours (of which the want of space will prevent us offering little more than a brief enumeration): In 1821 he published a little volume containing "Two Discourses on the Unity of the Church, her Divisions, and their removal. To which is subjoined, A short View of the plan of Religious Reformation originally adopted in the Secession." 12mo, pp. 174.

This was followed in 1825 by a volume entitled "Memoirs of Mr William Veitch and George Bryson, written by themselves: with other narratives illustrative of the History of Scotland, from the Restoration to the Revolution: to which are added, Biographical Sketches and Notes, by Thomas M‘Crie, D.D." 8vo, pp. 540. In the preface the editor observes, “that, with a little more labour, a connected history of the period might have been produced; but I am persuaded that no account which I could draw up would present so graphic a picture of the men and measures of that time, as is exhibited in the following historical pieces.” These are indeed highly graphic and interesting, but the volume might be instanced as a proof of what Dr M‘Crie confesses, that the time and labour bestowed upon it would have gone far to produce an original work of greater importance. In reviewing this volume, the editor of the Edinburgh Christian Instructor sums up with saying, “in Dr M‘Crie we see all we could wish for in the historian of the presbyterian church; and if he would add to his former labours a history of that church from the beginning of Charles the First’s reign to the Revolution, we are sure the public would receive it with feelings of the highest satisfaction.”

---

[1] A History of the Life and Times of Henderson has lately been published by the Rev. Dr Aiton, minister of Dolphington.

[2] In the Edinburgh Review for April 1830, there is an article by Dr M‘Crie, on the Memoirs of Sir James Turner, published for the members of the Bannatyne Club, from an original manuscript.

[3] In a volume of "Sermons, by the late Rev. James Aitken, Minister of the Associate Congregation of Original Seceders, Kirrymuir. With a Memoir of the Author, and a number of his Letters." Edin. 1836, 12mo, pp. 400–2.

This hint, however, was not taken, as the next subject of his investigation led to the publication, in 1827, of a “History of the Progress and Suppression of the Reformation in Italy in the Sixteenth Century, including a Sketch of the Reformation in the Grisons,” 8vo, pp. 434 (of which a second edition appeared in 1828). Also, in 1829, as a sequel to that work, a “History of the Progress and Suppression of the Reformation in Spain in the Sixteenth Century,” 8vo, pp. 424. These volumes undoubtedly form a valuable accession to the history of the Reformation throughout Europe, although the author laboured under great disadvantages in having but limited access to original sources of information, compared to what was within his reach in matters of our own ecclesiastical history; and it was felt, that they tended rather to excite a desire for information than fully to gratify it, and that the materials were not equal to the skill and industry displayed. It is clear that the state of public opinion had prepared the way for a reformation even in Italy, the stronghold of the Roman Catholic church, and the progress that great cause made was indeed remarkable and extensive; but nothing could withstand the systematic, unceasing, and exterminating measures employed to arrest the progress of reformed opinions; and the more so as these were not counteracted by any opposing interests of the civil and ecclesiastical authorities either in Spain or Italy, whilst the strength of the reformers, having no unity of purpose, was wasted by unhappy divisions among themselves. Both volumes, however, present very interesting and affecting particulars of the sufferings of those who were doomed to exile, imprisonment, or death, for religious liberty and for the truth.

Dr M‘Crie was at length induced to undertake a more arduous task, which had been looked for from his hand, and which he himself had long contemplated. This was a Life of John Calvin the reformer. To do justice to such a work, he considered a lengthened residence at Geneva, where the most important original documents are preserved, to be quite essential; but a due attention to his ordinary ministerial functions precluded him from the chance of ever being able to leave home for so long a period. The prospect of his son, Mr John M‘Crie, going abroad, and remaining several months at Geneva, in some measure obviated this difficulty, as he could not only trust to his accuracy in transcribing Calvin’s original letters, but, by regular communication, hope to obtain all the requisite information from other sources, and in as satisfactory a manner as if he himself were on the spot to direct such researches. His son accordingly set about the task most assiduously, and, with a zeal, knowledge, and perseverance worthy of all praise, transmitted such a mass of materials as could not have failed, in Dr M‘Crie’s hands, to have rendered his work one of the highest importance in ecclesiastical biography. He had in fact made considerable progress in writing the earlier portion, and was intently engaged upon it (in the midst of the constant interruptions to which he was subjected), at the time when all his earthly labours were brought unexpectedly to a close. It is understood that one of his sons has the intention, from the materials already collected, to complete a Life of Calvin; otherwise, even as a fragment, the portion actually written should not be withheld from the public.[1]

Dr M‘Crie’s sedentary habits and application to study were not favourable to health, if he ever could be said to have been very robust. In the summer of 1835 he had been confined for a time through indisposition, but there was no apparent change to indicate the suddenness of his decease. In fact, a short absence in the country seemed to have re-established his health, and he was so far recovered, that, on Sabbath the 2d of August, he preached as usual, both in the forenoon and afternoon, and walked out on the following Tuesday to visit a neighbour; but on the afternoon of that day, about five o’clock, he was taken alarmingly ill, and between ten and eleven at night he fell into a stupor, from which medical aid failed in recovering him. In this state he remained till half-past twelve next forenoon (Wednesday the 5th of August), when he breathed his last. His death, thus unexpected, at a time when it was hoped his life might have been spared for several years of increasing usefulness, and when his mental faculties were in full vigour, could not fail to excite a very deep interest; and many appropriate expressions of public regard were called forth, both in the pulpit and through the press.[2] It happened that a meeting of the commission of the General Assembly was held on the day of the funeral (the 12th), and, on the motion of the Reverend Dr Cook of St Andrews, a deputation, consisting of the moderator and several of the leading members, attended, as a suitable mark of respect due from the church to which he had been so zealously and consistently attached, and for which he had done so much by his writings. He was interred in the New Greyfriars burying-ground.

Dr M‘Crie was twice married. By his first wife (Mrs Janet Dickson), who died 1st June 1821, he left four sons and one daughter. His eldest son, Thomas, who has been for several years in the ministry, has recently been elected by the congregation as his father’s successor; and has also, upon Dr Paxton’s resignation, been appointed by the Synod professor of divinity. By his second wife (the daughter of his old friend and associate, the Reverend Robert Chalmers, Haddington), who survives him, he left no issue. A half-length portrait, from a picture by Mr Watson Gordon, S. A. to be engraved in mezzotinto, is in the course of publication, and cannot fail, as it is an admirable likeness, to be an acceptable memorial to his friends and admirers. A bust, also, by Alexander Ritchie, was in the last exhibition of the Scottish Academy. In this year (1836) a posthumous volume of “Sermons,” by Dr M‘Crie, edited by his son, has appeared, 8vo, pp. 393. A collection of his miscellaneous writings, with memoirs of his life by the Rev. Thomas M‘Crie, have likewise been announced for publication.

It is not necessary to enlarge upon Dr M‘Crie’s general character. In private life he was kind, affable, and free from every thing like display or desire of notoriety; being remarkable for his cordiality of manners, cheerfulness of temper and conversation, and his unaffected simplicity. As a preacher, his style of address was rather unprepossessing, partly from want of action, and partly from his slow, monotonous, and somewhat constrained delivery, as if afraid to speak out in the natural tone of his voice. But any deficiency of artificial eloquence was amply compensated for by his profound and luminous expositions of Scripture, expressed in clear and energetic language; and his discourses were uniformly of a practical nature, and breathed a strain of great piety. In his literary character, by which he will be known in after times, it will be acknowledged that his mind was of no ordinary cast. With extensive erudition, and habits of indefatigable research, he combined sound judgment, and a singular acuteness and sagacity of intellect. Could he have remained satisfied with the researches of previous writers, he might have produced a greater number, and perhaps more popular works, but they would not have borne the peculiar impress resulting from his own minute, accurate, and extensive inquiries, and therefore there is no occasion for regret that he should have devoted much of his time in exploring the original sources of information. His learning was both profound and extensive, as he was not only skilled in what are called the learned languages, but was conversant with most of those of modern Europe. Still, with all his natural love of literary pursuits, he kept such employment in subservience to his duty as a diligent and faithful minister of Christ. For nearly forty years he laboured with the most affectionate solicitude for the spiritual interests of his flock, and much of his time was devoted to them in his week-day ministrations. It was chiefly a consideration of the paramount importance of such a charge, we imagine, that caused him to decline the prospect of a chair in the University of Edinburgh, when a vacancy occurred in the professorship of Church History. There is every reason also to believe, that had his life been spared a few months longer, the honorary office of Historiographer Royal for Scotland would have been conferred, unsolicited, upon him, as a public testimony due to him. To conclude, the fame of Dr M'Crie as a literary writer has extended widely beyond the limits of his own country; and his name will probably be an object of greater regard in future times than even at present, though all his personal virtues are fresh in recollection. The profound research, the masculine vigour, and philosophic wisdom displayed in all his writings, added to the permanent interest of the subjects upon which the powers of his mind were usually employed, stamp them as works which will remain as landmarks in historical literature. (C. C. C.)

---

[1] It may be noticed, that Dr M‘Crie, in May 1834, visited London to give his evidence before the Committee of the House of Commons on Church Patronage. His evidence forms part of the voluminous Report on that question, pp. 355-374, and 383-393.

[2] See *Blackwood’s Magazine*, and *Edinburgh Christian Instructor*, for September 1835. In the latter are extracts from the *Christian Herald*, &c. There has also appeared an eloquent Sermon, “occasioned by the death, and preached to the congregation, of the late Rev. Thomas M‘Crie, D. D.” on September 6, 1835, by Robert Shaw, minister at Whitburn, 8vo, pp. 30.

MACRIN, Salmon, one of the best Latin poets of the sixteenth century, was born at Loudun. His real name was John Salmon; but he took that of *Macrin*, from his having been frequently so called in ridicule by Francis I. on account of his extraordinary leanness. He was preceptor to Claudius of Savoy, count of Tende, and to Honorius the count's brother; and he wrote several pieces of poetry in lyric verse, which were so admired that he was called the Horace of his time. He died of old age, at Loudun, in 1555. *Charles Macrin*, his son, was not inferior to him as a poet, and surpassed him in his knowledge of the Greek tongue. He was preceptor to Catharine of Navarre, the sister of Henry IV., and perished in the massacre of St Bartholomew in 1572.

MACROBII, a people of Ethiopia, celebrated for their justice, and the innocence of their manners; also a people in the island of Meroe. The Hyperboreans were likewise called *Macrobii*. They generally lived to their hundred and twentieth year, and from their longevity they obtained their name (μακρος βιος, *long life*).

MACROBIUS, Ambrosius Aurelius Theodosius, an ancient Latin writer, who flourished towards the close of the fourth century. Of what country he was, is by no means clear. Erasmus, in his *Ciceronianus*, seems to think he was a Greek; and he himself tells us, in the preface to his *Saturnalia*, that he was *not* a Roman, but laboured under the inconveniences of writing in a language which was not natural to him. Of what religion he was, whether Christian or Pagan, is uncertain. Barthius ranks him amongst the Christians; but Spanheim and Fabricius suppose him to have been a heathen. This, however, is certain, that he was a man of consular dignity, and one of the chamberlains or masters of the wardrobe to Theodosius, as appears from a rescript directed to Florentius, concerning those who were to obtain that office. He wrote a commentary upon Cicero's *Somnium Scipionis*, and seven books of *Saturnalia*, which treat of various subjects, and form an agreeable mixture of criticism and antiquities. He was not an original writer, but made great use of other people's works, borrowing not only their materials, but even their language; and for this he has been satirically rallied by some modern authors, though rather unfairly, considering the express declaration and apology which he makes on this head, at the very commencement of his work. "Don't blame me," says he, "if what I have collected from multifarious reading, I shall frequently express in the very words of the authors from whom I have taken it; for my view in this present work is, not to give proofs of my eloquence, but to collect and digest into some regularity and order such things as I thought might be useful to be known. I shall therefore here imitate the bees, who suck the best juices from all sorts of flowers, and afterwards work them up into various forms and orders, with some mixture of their own proper spirit." The *Somnium Scipionis* and the *Saturnalia* have been often printed; and to them has been added, in the later editions, a piece entitled *De Differentiis et Societatibus Græci Latinique Verbi.*

MACROCERCI, a name given to that class of animalcules which have tails longer than their bodies.

MACROCOLUM, or Macrocollum (formed of μακρος, *large* or *long*, and κολλαω, *to join*), amongst the Romans, the largest kind of paper then in use. It measured sixteen inches, and frequently two feet.

MACROCOSM, a word denoting the great world, or the universe.

MACTAN Isle, a small island, one of the Philippines, situated to the east of Zebu Isle. It is noted as the place where Magellan was killed, A. D. 1521, on his return from America by a westerly course. Long. 123. 48. E. Lat. 10. 30. N.

MACTATIO, in the Roman sacrifices, signifies the act of killing the victim. This was performed either by the priest himself, or by some of his inferior officers, who were known under the name of *popæ*, *agones*, *cultrarii*, and *victimarii*; but, before the beast was killed, the priest, turning himself to the east, drew a crooked line with his knife, from the forehead to the tail. Amongst the Greeks this ceremony was most commonly performed by the priest, or, in his absence, by the most honourable person present. If the sacrifice was offered to the celestial gods, the victim's throat was bent up towards heaven; if to the infernal, or to heroes, it was killed with its throat towards the ground. The manner of killing the animal was by a stroke on the head, and, after it had fallen, thrusting a knife into its throat. Much notice was taken of, and good or ill success predicted from, the struggles of the beast, or its quiet submission to the blow; from the flowing of the blood, and the length of time the animal happened to live after the fall; and other circumstances.

MACULA, a bay of Arabia, on the northern coast, about two leagues deep and fifty broad, at the bottom of which is a small town. It is fifty-five leagues east-north-east from Cape Aden. Long. 47. 33. E. Lat. 14. 6. N.

MACUNA, one of the Navigator's Islands, in the South Pacific Ocean, where a captain and several officers and men under Pérouse were massacred by the inhabitants. Long. 169. W. Lat. 14. 19. S.

MADAGASCAR, an important and interesting island, on the eastern coast of Africa, separated from the mainland by the channel of Mozambique, which is nearly 300 miles broad. It is one of the largest islands in the world, extending from 12. 2. to 25. 40. south latitude, being above 800 miles in length from north to south, and varying in breadth from 120 to 300 miles. It is traversed from north to south by a double chain of mountains, some of which reach the height of 6000 feet above the level of the sea. Some of these elevations are the craters of extinct volcanoes, and have the shape of an inverted cone. These ranges divide Madagascar into two parts, approaching nearer to the eastern than to the western coast. The scenery is often very grand and picturesque, presenting high, abrupt precipices, luxuriant valleys, passes and ravines, immense forests, streams, and lakes. Numerous rivers have their rise in these mountains, which amply supply the surrounding country with water for the purposes of irrigation. Probably no country in the world is more plentifully supplied with this indispensable requisite. The most considerable of these rivers are the Murundava on the western side, and the Mananzari and Manangara on the eastern. The Andevourante is navigable for canoes to the distance of a hundred miles from the sea. The Manguru, one of the finest of them, rises from the lake Antsianaxe, which is seventy-five miles in circumference. Four other lakes, Rassoi-Be, Rassoi-Massaïe, Irangue, and Nossi-Be, extend along the eastern side, and communicate with one another.

This island is very rich in mineral productions, though these are turned to very little account. Iron ore abounds in considerable quantities very near the surface of the soil, and, when wrought, the metal is found soft and malleable, and equal to any in the world. The mountains contain tin and lead; and small quantities of pale gold and copper have been obtained. Immense blocks of rock crystal, some of them twenty feet in circumference, abound in the country; granite, very fine black agates, and many other less precious stones, are also found. Along the western part are numerous banks of mineral salt, which is to be obtained with very little labour.

The botany of the island still presents an almost unexplored field for the naturalist. From the fertility and marshy nature of the soil, vegetation in every quarter is most luxuriant. In the fields and forests are found many trees and shrubs, useful both in the arts and for the purposes of life. Amongst the most valuable are the sagou tree, the leaves of which are used to manufacture stuffs in high repute; two species of coffee tree; a plant called the ravinale, from which the inhabitants make many useful instruments; and several varieties of the cotton tree, particularly that known as the largest species. This country also furnishes some costly woods, such as sandal, black and white ebony, green and white spotted. The indigo plant, rice, and yams of several sorts, are also found, indigenous to the soil. Rice, of which there are eleven species, is the chief article of culture, and the principal food of the inhabitants. It is grown on the low lands, in the damp woods, and on the banks of rivers. After rice, manioc and batatas are most commonly cultivated for food, the roots of the manioc often measuring fifteen feet in length and one foot in diameter; the vine, sugar-cane, pine-apples, bread-fruit, sweet potatoes, plantains, Indian corn, prickly yam; tobacco, of which there are eleven species indigenous to the island; the arrow root, called by the natives tharoole; the Urania speciosa, the leaves of which are made to supply the place of dishes; allspice; negro pepper of the Indies; the angola pea, on which silk-worms principally feed; and the Sagus rufia, a species of pine, the fibrous part of the leaves of which are woven into garments, worn by the principal inhabitants. Indeed all the vegetables peculiar to tropical climates, and even those of Europe, have been here successfully cultivated.

The animals most abundant in Madagascar are horned cattle, which are very fine, and furnish inexhaustible wealth and food for the population. All these have bunches of flesh on their shoulders, those on bulls being exceedingly large. Hogs and poultry are bred, but less generally regarded. The elephant and lion are unknown, but an animal is found called the antaba, which appears to be a species of leopard; and another called farassa, somewhat resembling the jackal. Wild asses with very large ears, wild boars with horns, goats, sheep, a species of hedgehog proper for eating, and the bat, which is esteemed a delicacy, are also found in Madagascar. Alligators are numerous, and in some places their flesh is eaten, in others it is held in abhorrence. In the woods fowls are very numerous; the most useful are wood-pigeons, pheasants, geese, ducks, and parrots. Locusts sometimes darken the air, and are considered as excellent food by the inhabitants. The rivers swarm with fish; but they are infested with crocodiles, which often prove fatal to strangers.

With regard to the state of agriculture in Madagascar, we quote the following observations of a distinguished traveller who recently visited the island:—

"The island of Madagascar is very fertile, even to the highest point of land; but it is only slightly cultivated, owing to the slothful habits of the people, who raise barely sufficient crops for their own consumption, and who, untaught by frequent seasons of scarcity, never fail to indulge their idle and gluttonous propensities whenever opportunities for doing so occur; preferring a present gratification to the exercise of that wise forecast that would provide for the future. Agricultural labour is not here confined to the male sex; on the contrary, the greater proportion is performed by women. The only farming implement used is a spade weighing about five pounds, six inches wide and nine deep, with a handle from seven to ten feet in length of red wood. The rice-grounds are dug up into sods of about a foot square, and five inches thick. The soil is usually enriched with marl or common manure; and being then turned, is left exposed to the sun for eight or nine days, when water is thrown upon it, and it dissolves easily. Cattle are then driven over it, the rice sown, and the earth carefully levelled, the sowers all the while wading knee deep in mud. These men are by no means expert; but that is perhaps owing to the natural indolence and carelessness which pervades their general character. Rice is frequently half grown in low grounds, and afterwards transplanted to a more favourable situation; but it is not so good as that which has not been thus transplanted."[1]

The western coast of Madagascar was carefully explored during an expedition undertaken by command of the British government, and this will enable us to describe it pretty fully.[2] The first bay touched at by the expedition was St Augustine's, which is situated about 150 miles from

---

[1] Holman, *Voyage round the World*, 1834.

[2] *Narrative of Voyages to explore the Shores of Africa, Arabia, and Madagascar*, performed in his Majesty's ships Leven and Barracouta, under the direction of Captain W. F. W. Owen, R. N. In two volumes. London, 1833.

Cape St Mary, the southern extremity of the island. It is large and spacious, and was formerly much resorted to by English vessels, principally engaged in the slave trade. Now, the intercourse of the people of St Augustine's is chiefly confined to the whalers, and an occasional slaver that touches at it, either for refreshments or an addition to her cargo.

Tullia Bay is formed by a long narrow reef, dry at low water, and having two channels, one communicating with St Augustine's, and the other opening to the sea nine miles to the northward. In every part it affords safe and commodious anchorage for the largest ships. In the vicinity of the bay the country is low, but at a short distance inland it rises into a lofty range of hills. From St Augustine's to Boyauna Bay the coast is almost an unvaried, low, marshy plain, irrigated by barred rivers, bounded by a line of sharp pointed coral masses, which are uncovered at low water. At a few places a complete archipelago of rocky islets is formed, which assume a variety of fantastical shapes, that of the cauliflower being most predominant. These coral islands are very numerous, but they seldom exceed one mile in circumference. To mariners unacquainted with them they are very dangerous, but to others they afford at all seasons a safe and commodious anchorage, the extensive group called the Barren Islands, in particular, forming excellent harbours; yet they are only worth resorting to for wood, being destitute of fresh water. The shore is thickly covered with trees of a stunted growth, above which, in the immediate vicinity of the sea, the elegant casuarina is occasionally observed. In the vicinity of the Bay of Boyauna the hills present a very luxuriant appearance. There are two rivers in this bay, each affording capacious harbours. Off the northern one, termed Makumba, lies an island of the same name, almost connected with the main land by sandy flats. It is of considerable size, but lofty, and presents in every direction a huge precipice, excepting in one small spot, where a deep rent in the rock admits of a dangerous pass to the summit, which is a perfect level; and on it are the ruins of two small buildings, supposed to be of Arabic construction.

The northern half of the west coast of Madagascar is indented by a series of bays, rivers, and harbours, so admirably adapted for commerce in every respect, that were the island inhabited by a civilized people, it would doubtless be resorted to by ships of all nations for purposes of traffic. With the exception of Bembatooka, these harbours are utterly neglected, except by an Arab dow that occasionally touches at them for the purpose of procuring sandal wood or jerked beef. The bay of Bembatooka is in reality the estuary of several rivers which fall into it from distant parts of the interior. It is seventeen miles in depth, and three and a half miles across at the entrance; but inside it widens to nearly eight, excepting about half way in, where the shores on each side approach and leave a narrow channel, through which the pent-up water rushes with so much violence as to have scooped out an abyss of sixty-three fathoms in depth. The shores are in general low, and clothed with mangroves; but in some places they rise into a lofty range of hills. The village which takes its name from the bay is inconsiderable; but Majunga, situated on the northern side of the bay, near the entrance, is a large straggling town, nearly a mile in extent, and containing a large population of Malegashes and Arabs. The Malegashes are described as a very fine race of men. The style of the buildings, like the inhabitants, is one half Arab and the other half Malegash. The slave trade, and a traffic with the Arabs in bees' wax, rice, and gums, formerly constituted the principal source whence Bembatooka derived its wealth; but these are either abandoned, or of little importance when compared with the extensive trade in bullocks now carried on with the Americans, who jerk the beef, preserve the tallow, and cure the hides on the spot. Notwithstanding the distance of the voyage, the Americans have found this a profitable speculation, and have established small shops, where are retailed a variety of assorted goods, which are exchanged for the minor articles brought for sale by the natives. They also have a large wooden building, with an enclosed space attached, in which they slaughter their bullocks.

The next place of importance in proceeding northwards is Majambo, which strikingly resembles Bembatooka, being of about the same dimensions and form, possessing a like chasm of deep water in the centre, and having, like it, several rivers at its head. This bay would appear to have been anciently inhabited by Arabs, as their tombs are still in existence on the summit of the small island of Manza, blackened by age, and fast mouldering to decay. Farther to the north is Nareenda Bay, the islands at the north entrance of which afford excellent harbours, and are approachable in almost every direction. Saucasse, the largest of them, is inhabited, and nearly covered with verdure; as is also that of Souhee, a stupendous rock upwards of two hundred feet in height. A group of lofty volcanic islands, together with two or three lesser islets, intervenes between Nareenda and Passandava, the broadest and deepest bay on the west coast of Madagascar, and possessing numerous fine harbours. The village of Passandava, situated at the head of the bay, consists only of a few half ruinous huts. Near to it the mountains which surround a stupendous and inaccessible peak called Matowla take their rise. Numerous islands are situated in the vicinity of this chaotic mass of chasms and craggy steeps. Some of them abound in large masses of hardened earths of different colours, incorporated and stratified with quartz and basalt, or lava resembling it, whilst in others abrupt hills and lofty mountains enclose a pleasing variety of fertile valleys. Amongst the islands with which the western coast of Madagascar is profusely studded, may be mentioned the East and West Minnow groups; but they merely present an assemblage of perpendicular rocks or patches of coral. The islands next of importance are the Seychelles; but as they constitute a dependency of the island of Mauritius, they will be described in that article.

The western coast of Madagascar having now been described, it is only necessary to remark, that nearly all the towns are situated on rocky promontories, where the air is salubrious, and water can be easily obtained. The principal tribes who inhabit the western coast of Madagascar are the Muques and the Seclaves, both warlike tribes, the former possessing the southern and the latter the northern parts of the island.

We now proceed to describe the east coast of Madagascar, which, along with the west, is divided into various provinces, ruled over by independent chiefs, and inhabited by various races of men. In proceeding southwards from Cape Ambre, the northern extremity of the island, the first place worthy of notice is Diego Suariez Bay, or British Sound, which is perhaps one of the finest harbours in the world. Few natives inhabit the shores of this bay, and these are miserably poor, and have only bullocks to give in exchange for fire-arms, which they are particularly anxious to obtain. On its eastern side, which is much exposed to storms, the trees are shrivelled, and so matted and interwoven together that they are quite impervious to man. The substratum of the surrounding hills is composed of sandstone and columns of madrepore, many of which latter form hollow cylindrical points; most of the others are apparently primitive rock of volcanic production, in heterogeneous masses, which seem to have been at some period in a state of fusion. Antongil Bay, and the neighbouring country, next demand attention. A considerable part of the coast in this quarter presents a bold aspect. Those hills which, in coming from the southern extremity of the island, compose the most distant and highest range, here rest upon the sea, forming several stupendous rocky promontories. The general appearance of the country indicates fertility, every height being covered with stately and luxuriant forest trees, whilst streams of fresh water issue from the rich valleys wherever they open to the sea. In the vicinity of Antongil Bay is the river Maransectzy, the banks of which are low marshy swamps, but covered with a great variety of valuable trees, the largest of which is the gum-copal; mangoes and bananas are plentiful; as also the water-melon, which totally envelopes several lofty trees with its magnificent white flowers; whilst the modesta, with its beautiful pendant blossoms, and warra, are seen in every direction. English cottons, woollens, arms, and ammunition, meet with a ready and profitable market upon this coast; bullocks, gum-copal, and many other native productions, being obtained in exchange.

Isle Madame St Mary is thirty-one miles long north-east by north, and from two to three miles in breadth. Its surface presents a succession of hills, from two hundred to four hundred feet high, with deep and in general narrow vales, thickly covered with brushwood and underwood. Twice the French formed a settlement on this island: but the first time, the climate obliged them to abandon it; the second time, they were all massacred by the natives. In 1821, they again took possession of it, but suffered severely from the climate. Isle Madame, a low coral islet, constitutes their citadel, to which they retire every night for safety. The harbour is small, but deep, sheltered from all winds, and has a good supply of fresh water. The natives are short, rather darker than mulattoes, with low foreheads, broad and flat countenances, large eyes, and capacious mouths. Their canoes are small, of the common form, and delicately made, yet they venture far from the land, and will attack whales, which they kill by means of drags to the harpoon line.

The fan-palm is very plentiful, and invaluable to the inhabitants: houses are entirely constructed of it, the stems serving as supporters, the leaves forming the sides and roof. There are several looms for weaving cloth, made of the fibres of the sago-palm leaf, which is extremely durable; the natives also traffic in shells, wax, and turmeric. Beasts and birds are neither numerous nor varied; but there is an abundance of fish and vegetables, which are the principal subsistence of the inhabitants. The soil is exceedingly fertile, and is capable of producing all the fruits of a tropical climate. The black population of St Mary's is from twelve to thirteen hundred, a portion of whom are slaves to the rest. They pay no duties to the French, and are governed by their own laws.

The places next of importance in proceeding southwards are, Foul Point and Tamatave, two excellent bays or roads. The town of Tamatave is situated in latitude 18. 10. S., and longitude 49. 31. E. The entrance is between reefs, and ships are exposed to east winds; but the anchorage is good. The town contains about sixty good dwelling-houses, besides a number of native huts; they are large, divided into chambers, and well thatched with the leaf of the ravinale. The walls and floors are neatly matted, and the apartments are generally kept in good order. Each house is surrounded by a palisade, which secures both its privacy and safety. The climate is considered as very unhealthy, especially during the summer months, that is, from November till March. Fevers are very common, and they are generally preceded by violent fits of shivering. There is no exclusive right of landed property at Tamatave, which is considered as common to the whole chieftainship, and every person is at liberty to cultivate at his pleasure any unappropriated spot of ground, which is considered as the cultivator's until the crop is gathered. There is no impost or tax of any description, either on land or its produce. The children inherit, without dispute, any thing of which the parent dies possessed; but a free gift to the king of the northern peninsula is expected from the heir, according to his circumstances. The chieftain may, in cobar or council, concede landed property to strangers. The French had an establishment for salting meat here during the war, and Mauritius and Bourbon were supplied with it from this place. Bananas and plantains are abundant; and, when dried in the smoke, they are excellent, and will keep for any length of time. Locusts of a very large species abound here, and they are greatly esteemed by the natives as food. These insects, however, often prove very destructive to the crops, devouring all vegetable matter with astonishing rapidity.[1]

This part of the country is the most frequented by Europeans, who make large purchases of rice and cattle from the natives. It is or was termed the province of Bestimessaras, and is governed by malates, or chiefs of white extraction, who tyrannize over the people. They are looked upon as the handsomest men in Madagascar, but dissembling, drunken, cowardly, and addicted to theft. Farther to the south we meet with the Betanimenes or Sicouas. This country is the finest and most fertile of all the provinces situated on the sea-coast, and the inhabitants are very mild and sociable. Betanimenes owes much of its fertility to the river Andevourante, which is named after the capital, a pretty large town, and capable of furnishing a considerable number of armed men. The province of Antaximes is the last which is situated on the eastern coast of the island. The soil is good, but the cultivation of it is much neglected by the inhabitants; indeed this is the case throughout the whole island. The bay of Port Dauphin is large, and the anchorage is good. The town, which is of the same name, is of considerable size, and is the residence of a native chief, Ramananoulouna, whose power is absolute in this part of the island. After the death of Radama, king of Ovah (an important province, afterwards to be described), the widow of the deceased espoused Ramananoulouna; but, in 1829, this capricious individual declared himself independent of the reigning queen, and established himself in this distant part of the country. He has a considerable military force, well accoutred, and furnished with muskets. The produce here is nearly the same as in other parts of Madagascar; the staple commodities being rice and bullocks, which are exchanged for manufactured cottons, old cloths, and the like articles, which are brought principally from Bourbon. The only manufactured goods are guard-chains, grass cloths, mats, and baskets. The huts of the inhabitants are composed of stakes driven into the ground, the sides and tops being covered with fern leaves and grass. There is no distinctive fashion in the dress of the sexes, nearly all wearing no more than a cloth tied round the waist. The higher classes, however, and those connected with the court, including the soldiers, are attired in a very showy manner.

By far the most important part of Madagascar is that part of it occupied by the Ovahs, a race who inhabit the interior. This people owe the superiority which they have obtained to Radama, the first chieftain belonging to the island who assumed the title of king. He was an interesting and extraordinary man, the Mehemmed Ali of his country; but a more particular account of him will be introduced after the province has been described. It is alternately hilly, mountainous, or swampy and poor, though many places are rich in rice-grounds, pasturage, and the like, and much of the land is capable of extensive cultivation. As most of the animal and vegetable productions formerly mentioned as belonging to the island generally are found here, it is unnecessary to advert to these again. The ground is well watered by a number of streams, rivers, and lakes, but is in most parts destitute of fine timber, though there is much long grass and underwood. The fuel of the people is grass, moss, cow-dung, and in some places brushwood. Their food is rice, sweet potatoes, manioc, plantains, beef, wild fowls of the guinea species, which are everywhere in great plenty, fish, wild hogs, monkeys, and the like. In general they eat very little animal food, but live chiefly on vegetables.

---

[1] *Voyage round the World*, by James Holman, vol. ii. p. 486, 1834.

The Ovahs are in height rather above the European standard, portly in their person, of shades of colour varying from deep black to copper (the latter colour, however, being most prevalent), with good-natured countenances. They are clothed only with an upper and lower garment, the saimbou and seddick; the former being a sort of robe, with which they partially envelope the body, wearing it in the manner of a scarf, the men throwing one end over the left shoulder, to give freedom to the right arm, whilst the women throw it over the right; the seddick, or under garment, is called also langouti. They generally carry in the right hand a zazaie, that is, a lance of about six feet in length, of polished wood, and very straight, terminated by a javelin blade, and shod with iron; and they are particularly fond of decorating their persons with silver and glass bracelets and rings, and with amulets or charms, especially the teeth of the cayman, a species of crocodile found in the rivers. Some wear plain, and others ornamental, head-dresses. A few of the chieftains carry the adze or battle-axe, and some of them are provided with shields.

Their dwelling-houses are generally small, that is, about five feet high to the wall-plate, fifteen feet long, and twelve feet wide. The frame-work is of round timber, easily selected for the purpose, and thatched with the zouzoura, which is the papyrus or paper-plant of the ancients, or with a reed called hayrana.

The villages are for the most part built on small eminences in the neighbourhood of good water, and contain from a small number to sixteen hundred houses. They are guarded against hostile invasions by having one, two, or three ditches surrounding them, as well as by being enclosed by a stockade fence. Each family occupies a separate building; and their household furniture consists of some baskets, a cushion on which to sit, a mat to lie down on, with a matted bolster for a pillow, cooking-vessels made of potter's clay, which the soil produces, a felling-axe, wooden pestle and mortar for taking the husks off the rice, a winnower, and a loom for making cloth. Thanaan-arive, the capital, is situated at an elevation of 4000 feet above the level of the sea, in latitude 18. 56. south, longitude about 47. east, and is 160 miles from the nearest coast.

The other tribes consider the Ovahs as a powerful and industrious people, and look up to them as superior, from the knowledge they possess of manufacturing silken and cotton saimbous and seddicks, the forging of iron, and applying it to different purposes, from the blade of the zazaie or lance down to a needle, and the making of silver and gold chains, balances, and other articles wherein great ingenuity is displayed.

The commerce of the capital is chiefly carried on by means of a very considerable river called Betsibooka, which, about fifteen miles from its mouth, expands over a wide extent of country, encircling small islands, and emptying itself into Bembatooka Bay, which, at its entrance, is free from rocks and sand banks. Boats are able to proceed 160 miles up the Betsibooka, to a place called Mahatsara, where two other rivers fall in, in latitude 17. 33. south; thence the trader has only a distance of about eighty-five miles to travel overland to the capital. One of the principal impediments to intercourse with the Ovah country arises from the want of beasts of burden, no use being yet made of cattle for this purpose. Were these employed, the different provinces of the island might be greatly improved. Not only might rice and corn be cultivated to a prodigious extent, but the treasures of the earth, such as iron-ore, potters' clay, plumbago, and tin, might be easily obtained; and more attention might also be paid to the breeding of cattle. The Ovahs carry on a trade both by barter and with money; that by barter consisting chiefly of rice and cattle, which are exchanged for arms, clothes, and ammunition; that by money, of all sorts of other things, as scents, baubles, and the like. They are very superstitious, place the utmost confidence in divination, and their wise men exercise great influence over them.

It only remains to say a few words regarding Radama. This prince reduced to subjection the largest and finest part of the island. He held many cobars or public meetings, at which he required the attendance of all his conquered or submitting subjects, at which time they took the oath of allegiance or fidelity to him. On these occasions he proclaimed himself king of Madagascar, made known his laws (which he greatly reformed), and the terms on which he protected the subject, which were submission, and the payment of a tenth of their property. He abolished the slave trade, both in exportation and importation, and punished either with death. He greatly encouraged commerce, and through the medium of trade had, as early as 1817, obtained twenty thousand stand of arms, with which he equipped his troops; and he rendered his army still more formidable by adding to it a train of artillery. A number of young natives were sent by him to Paris and London to obtain instruction, and by the aid of the English missionaries he established a printing press. Numerous teachers were under his auspices trained and distributed throughout different parts of the kingdom. Unhappily this prince was, in the year 1828, poisoned by his wife, who raised a worthless paramour to the throne; the same individual who has already been mentioned as having established himself at Port Dauphin. The death of Radama has introduced great anarchy, inducing several subject states to shake off the yoke which he had imposed upon them, certainly for their own ultimate advantage; and there seems now every reason to fear that the career of improvement which was begun under such favourable auspices will be arrested. A native prince, with talents equal to those of Radama, rarely appears in a semi-barbarous country.

The observations which follow apply to Madagascar in general, not to Ovah in particular. The form of government throughout the island is democratic; consequently all matters of public importance are settled in the council or cobar, which is composed of all the male persons who choose to claim a seat there. The cobar is also their court of justice, and the only one in the chieftainship; its decisions in criminal cases are final, but not always in cases that respect the rights of property, these being frequently referred to some neighbouring chief, whose opinion is thought impartial, and his decision is always conclusive. All crimes, except that of murder, are punished by fine, which, if not paid by property, must be liquidated by personal labour, the criminal being constituted the slave of the accuser. Murder is punished by inflicting upon the culprit the same death that he perpetrated upon his vic-

Madagascar.

tim. Inflicting an intentional injury upon a person is punishable in the same manner. Circumcision is universally practised; but it is not confined to any particular age, although it generally takes place when the child is about ten months old, and seems only dependent on the pleasure of the parents, or upon contingent circumstances. The adornment of the person about to be circumcised is one of the most indispensable parts of the ceremonial; but there are many others which are whimsical and amusing enough, as feasting, dancing, and singing. The ceremony of marriage is very simple; amongst the slaves there is none at all beyond the master's consent and the mutual promises of the parties themselves; neither is the tie considered as binding. The offspring are bond or free according to the condition of the mother. Amongst the higher classes, the consent of the parents is considered as an essential point; and the marriage is effected at a family meeting, when the elder people give advice to, and express good wishes for, the young couple, frequently accompanied with more substantial proofs of their esteem. Polygamy is allowed, and extensively practised. Separations are not unfrequent, being lawfully permitted; after which the parties are allowed to marry again; otherwise, adultery is punishable, but not with death, except where a member of the royal family is concerned, particularly the wife or mother of the king. The succession to the crown is hereditary; yet, by an ancient law, it is only permitted to be so in the female line, that is, the king's sister's eldest son. Slaves are very numerous in the country. Criminals of sundry descriptions are liable, with their wives and children, to be sold into bondage. Their lot, however, is not very severe, as they are employed entirely in ordinary and domestic occupations; and are, in reality, mere menial servants and labourers, eating and living with their owners whilst they conduct themselves well; when they do otherwise, they are sold as a punishment. Thirty or forty dollars are the common prices for good men slaves. With regard to religion, little that is satisfactory can be said. An attempt has lately been made to introduce Christianity, but, we fear, with small success. Radama encouraged the missionaries and patronized their schools, which at one time were numerously attended, and bade fair for the extension of civilization; but they have met with opposition and persecution from his worthless successor. In some places Mahommedanism prevails, but for the most part the people are under the bondage of Ompamousavous (sorcerers, or wise men), who celebrate certain heathenish rites, which it is unnecessary to describe. Although there is a mixture of Arabs and Moors, if not Jews, amongst the inhabitants of Madagascar, yet the great majority of the inhabitants have either a tawny complexion and the smooth hair of the Indians, or a black skin and the frizzled hair of the Caffres, which leads us to infer that the island was anciently peopled by emigrations both from Caffraria and Malabar. The name of Malegashes, assumed by the ancient inhabitants, and still in use, that of Mal-Dives, of Mal-Bar, and others, point out this descent, which, as far as regards the Asiatic emigration, is still more completely demonstrated by the composition of the prevailing language of the country. With regard to the Madecasse language, Malte-Brun observes, that "the language affords some Arabic words, and others more nearly resembling the idioms of the Caffres; but its principal roots may be traced in the Malay, or in the dialects derived from that language, and spoken at Java, at Timor, in the Philippines, in the Marian Isles, and in all the archipelagos of North and South Polynesia. Many of the most remarkable natural objects, and the days of the week, have the same names in the two languages. There is the same want of declensions and flexions, the same mode of uniting words, the same abundance of vowels. Notwithstanding what has been advanced by the learned continuator of the German Mithridates, we can affirm that the Madecasse appears intimately connected with the Malay language, and particularly with the Javanese and Timorian."

Madalena || Madeira.

It does not appear that Madagascar was known to the ancients. Some indeed have supposed that it is obscurely indicated in the book *De Mundo*, ascribed to Aristotle under the name of *Phanbalou*, and in the Periplus of the Erythrean Sea, under that of Menouthesias. It is supposed to be described by the Arabian geographers under the title of the Island of the Moon. During the middle ages it seems to have fallen, along with all the eastern coast of Africa, under the dominion of that people, whose posterity still form a leading class amongst the inhabitants. In 1506 it was visited by Tristan d'Acunha, but being found destitute of the precious metals, and without spices, it attracted little attention. A fine field of commerce is opening on the island for British enterprise, if conducted with honesty and good faith. The Malegashes have in general a great aversion to the French, who have repeatedly attempted, by force or fraud, to form settlements on their island, and who have often enticed them on board to trade (they being very fond of commerce), set their canoes adrift, and taken the owners of them into slavery. An instance of this kind occurred so recently as 1825. Nothing certain can be said as to the number of inhabitants; the most probable conjecture is, that they amount to about 2,000,000. By some travellers, however, the population is estimated at 5,000,000.

MADALENA, LA, an island in the South Pacific Ocean, about eleven leagues in circuit. It is very populous. Long. 141. 9. W. Lat. 10. 25. S.

MADEIRA, an island situated off the western coast of Africa, about fifty-four miles in length by twenty-one in breadth. It is a country of rocks, consisting of a number of lofty mountains, on the declivities of which all the productions of the island are raised. The best account of the island is that by the late Mr Edward Bowdich, whose journey over the island we shall follow. The country at the back and sides of Funchal, the capital, presents the broken outline of a segment of a vast natural amphitheatre of basaltic peaks and mountains, rising to 3800 feet behind the Mount Church, which is the most striking edifice in this beautiful landscape, and is elevated 1900 feet above the sea, presenting the most picturesque breaks and vistas, intersected by ravines and torrents, and covered with undulating and rugged ridges and sheets of basalt, diverging from the more central heights, and descending boldly to the sea. The basalt is both columnar and granular; the former is, generally speaking, compact, of a broad conchoidal fracture, splitting in horizontal laminæ, or at right angles to the prism, dark gray within or on the surface of a fresh fracture, which becomes covered with a superficial decomposing coat of brownish red, with age-inducing brittleness, and passing ultimately into yellowish white and dull brown; a moderately thin plate of the columnar basalt, when covered exteriorly with red powder, will snap between the fingers. The next place of importance is the Peak of Ariero, about three hours' ride from Funchal. The latter part of the ascent is along the barren rocks of basalt and red tuffa, which form the highest outline of the view behind from Funchal, and are 3700 feet above the sea. The peak is 5446 feet above the level of the sea, and is covered with vegetation to the top. The Coural, or sheepfold, is an immense valley near the village of Comera de Lobos, completely surrounded with almost perpendicular hills, and in no part less than 1000 feet in height. Round a part of three cliffs is a narrow road, winding along the brink of the precipices, often cut out of the solid rock, across peaks and gaps which were formerly impassable. This road has been of great importance in connecting the interior of the island with the sea coast, and useful for transporting the productions of the country to the capital.

The soil in every part is extremely fertile; the hills are covered with a luxuriant vegetation; and the finest flowers, sometimes of aquatic species, are found growing on the summits, being supplied with a moisture from the constant vicinity of the clouds. Trees and shrubs of the finest kinds are everywhere found in great abundance; and tropical plants which have strayed from the gardens soon become perfectly naturalized to the soil. The Portuguese formerly procured their principal supplies of sugar from this place; but not being able to compete with the West Indian planters, the inhabitants betook themselves to the culture of the vine, which has since become the chief product of the island. It is said that plants of the vine were conveyed from Crete to Madeira in 1421, and have since succeeded extremely well. There is considerable difference in the flavour and other qualities of the wines of Madeira; the best are produced on the south side of the island. The method of cultivation most generally followed is to trench the ground from three to seven and even nine feet deep, according to the nature of the soil, and lay a quantity of loose or stony earth at the bottom, to prevent the roots from reaching the clayey soil beneath, which would otherwise oppose their growth. The ground is watered three times if the summer has been very dry, the sluices being left open until the ground is pretty well saturated; the less the ground is watered the stronger the wine, but the quantity is diminished in proportion. The vines are found to bear fruit as high as 2700 feet, but no wine can be made from it. Wheat, barley, and rye are produced, but scarcely amount to one fifth of the quantity annually consumed. Wheat is sown in October and reaped in June; and the crop is followed by beans or sweet potatoes. The chestnut-tree has been introduced, and forms the principal timber of the island, and affords the chief food of the peasantry. Rice is cultivated, but more as ornamental grass than for any useful purpose. Pine and custard apples, and various other fruits, are grown in the open air in considerable quantities. In consequence of the land rising to a great elevation, this island presents great diversity of climate, though, upon the whole, it is mild and healthy. The rainy season comprehends the months of October, November, December, and January, although the dry weather during the first two months generally exceeds the rainy. The prevailing winds during this season are from the west and the south-west. In the dry season the prevailing winds are from the north-east, and they are not saturated with humidity like those which blow over the equinoctial seas. Although vegetation is so great, the pasture is scanty, and only capable of maintaining a small number of cows, which renders the productions of the dairy objects of luxury. A few oxen are used in the towns; but the mule is the most common beast of burden, and is best adapted for carrying goods along the narrow paths of the mountains. There are abundance of goats and hogs, which being allowed to run wild, acquire a resemblance to venison in taste; rabbits are very common in mountainous districts. Myriads of lizards inhabit the gardens and vineyards, and do considerable damage amongst the refined grapes. Bees abound in hills and valleys, and produce a honey of peculiar delicacy, from the numerous aromatic herbs on which they feed. The population is thought to be at present (1816) about 100,000, though some accounts represent it as much greater. From the extent of the island, and the rocky nature of the land, this census is very great. The inhabitants have evidently sprung from various sources. Amongst the richer inhabitants and merchants are found natives of almost every commercial country, but the greatest number are British. These hold little intercourse with the other inhabitants, but live in a state of luxury among themselves, and show great hospitality to strangers visiting the island. The peasants are generally of Portuguese descent, who, amidst the plenty which surrounds them, live in a state of great poverty. In appearance they are tall, well made, but meagre, with gloomy looks and long black hair; and they are very polite. Their dress consists of white linen trousers, made very wide, over which are drawn boots of buff leather; a coarse white shirt open at the neck, displaying their sun-burnt breasts; a blue cap and jacket, ornamented with silver buttons; and in winter they wear long cloaks. The females are condemned to severe labour: whilst the males are engaged in the vineyards, it is their duty to procure fuel, and often to carry loads of it to the city to dispose of for their subsistence, besides other households toils. They are generally of hard, yet not disagreeable features, with high cheek-bones, dark complexions, and rather large feet; their bodies, however, are well proportioned, and their eyes are lively, large, and black. The want of animal food is severely felt by the peasantry, the most hard-working labourer being constrained to live almost entirely upon bread, roots, and fruits. They extract from the husks and stalks of the grape, after they have passed through the wine-press, a kind of small beer called *aqua pé*, which, when fermented, acquires some degree of tartness, but will not keep.

The capital, Funchal, is a considerable town, situated in the centre of a large bay. It is built on the declivity of a hill, and the streets are kept clean, being watered by streams from the mountains. The bay is not very secure for anchorage, and is even dangerous during south winds. The landing is difficult, owing to the great surf which breaks upon the shore. It is strongly fortified towards the sea; but the defences on the land side have been greatly neglected. The wealthier inhabitants are generally British merchants, engaged in the wine trade. It is situated in long. 17. 6. W. and lat. 32. 37. N.

Adjacent to Madeira is the island of Porto Santo, about six miles long and two and a half broad. It is high and rocky, composed principally of sandstone, and a calcareous tuffa of a greenish-gray colour. The vine is cultivated in considerable quantities, and the soil yields good crops of wheat, Indian corn, barley, and beans. The population is estimated at 1400, and there are 300 militia. It possesses a good roadstead, but the landing place is bad. The Desertas are small uninhabited islands, which, with Madeira and Porto Santo, form the group called the Madeiras.

These islands were first settled by the Portuguese; but a tradition exists of their having been visited by an English gentleman, and lady to whom he was attached, who were left behind by accident, and both died there soon afterwards. It has belonged to the Portuguese ever since, and was considered as of such importance to the commerce of this country, that, during the late war, it was held in trust by Great Britain for her ally.

Its commerce consists almost entirely in the export of its wine. The principal quantity is sent to Great Britain, the East and West Indies, and America; but from frequent adulteration, and the preference of French wines, the trade is not now so great as it formerly was, the growth of the island not exceeding 20,000 pipes. The best is that known by the name of London particular, the second London market; and there is also a very rich sweet wine called Malmsey. The quantity of Madeira wines imported into Great Britain in 1833 was 301,057 gallons; of this, 161,042 gallons were retained for home consumption, and 209,194 exported. The price of these wines in London varies from L.18 to L.80 per pipe, according to the quality. There is also a considerable trade carried on in supplying with provisions ships which generally call at this place on the voyage to India.

MADEN, a town of Armenia, on the Tigris, so named from the copper and iron mines in its vicinity. Its situation is very striking and singular, being surrounded on all sides by bleak and barren mountains of great elevation, and overlooking a prodigious chasm, through which the Tigris forces a passage. It is sixty miles north of Diarbekir.

MADGHERY, a hill-fort and town of Hindustan, in the rajah of Mysore's territories. Long. 75. 15. E. Lat. 13. 33. N.

MADIGHESHY, a fortress of Hindustan, in the Mysore rajah's territories, situated on a rock of very difficult access, at the foot of which is a town containing near 200 houses. Long. 77. 16. E. Lat. 13. 48. N.

MADIRAN, a market-town of France, in the department of the Upper Pyrenees, and arrondissement of Torbes, with 1130 inhabitants, who grow excellent wine.

MADNESS. See MENTAL DISEASES.

MADRAS, a city of Hindustan, in the province of the Carnatic, and the principal settlement and capital of the East India Company in the southern peninsula of India. It is situated close to the margin of the sea, and is a fortress of great strength. In appearance Madras differs widely from Calcutta, having no European town, except a few houses, which are chiefly used as warehouses in the fort. The European residents, mostly the servants of the Company, live entirely in their garden-houses as they call them, which are all so closely planted that the neighbouring dwelling is rarely visible. They repair to the fort in the morning for the transaction of business, and return thence in the afternoon. These garden-houses are very neat buildings, being mostly of one story, and having a handsome balcony supported by pillars in front, with green Venetian windows. The fort itself, called Fort St George, is handsome, strong, and not too large; and, although not of so regular a design as Fort William, yet, from the greater facility of relieving it by sea, and the natural advantages of the ground, which leaves to an enemy no choice in the manner of conducting his attacks, it may, on the whole, be deemed equal to it; besides that it may be defended by a less numerous garrison. In the middle of the present fortress stands the original one, a small square, now mostly converted into government offices, and the town residences of some of the civil servants. The nabob of the Carnatic has also a palace called Chepauk, situated on the Chaultry Plain, at a little distance from the esplanade. The Chaultry Plain, once the scene of Tippoo's devastations, when he descended from the Ghauts, and, sweeping the low country with his cavalry, carried dismay to the walls of Fort St George, commences about a mile and a quarter south-west of this fort, from which it is separated by two small rivers; the one the river Triplicane, winding from the west, and gaining the sea about a thousand yards to the north of the glacis; the other coming from the north-west, and passing round the high ground of the western side of the Black Town, and continuing to the east within a hundred yards of the sea, where it washes the foot of the glacis, and, running for some time parallel with the beach, finally joins the Triplicane at its mouth. This plain extends two miles to the westward of the enclosures which bound the St Thome road, and terminates on the other side at a large body of water called the Meliapoor tank. It is now covered with the garden-houses of the European settlers, who have converted a barren sand into a beautiful scene of vegetation. The government-house is situated in the Chaultry Plain, on the edge of the esplanade, and has the advantage of not being quite shut up, having a pleasing view of the sea, and of Fort St George. The house itself is large and handsome; the floors, the walls, and the pillars, are of the most beautiful chunam of different colours, almost equal in splendour to marble itself. The roads are a great ornament to the place, being broad, and shaded on each side by a noble avenue of trees. To the southward of the fort stands the church, at the back of which is the residence of the governor. To the northward of the old fort stands the Exchange, on which, in 1796, a light-house was erected, the height of which is ninety feet high, and it is visible from the sea at the distance of seventeen miles. The botanical garden, reared at a vast expense by Dr Anderson, was nearly destroyed by a violent hurricane on the 9th of December 1807, and is now in a state of decay. In November 1803, a navigable canal was opened from the Black Town to Ennore River, which communicates with Pullicat. It is 10,560 yards in length, and thirty-five feet wide by twelve feet deep. By this channel boats go to Pullicat, whence Madras is supplied with charcoal. The Black Town of Madras stands to the northward of the fort, from which it is separated by a spacious esplanade. It is nearly four miles in circuit, and was formerly surrounded with fortifications sufficient to resist a surprise from a body of horse; but, owing to the tranquillity that prevailed in the country, these have long been neglected. It has some good streets and bazars; but the streets are not regular, nor are the houses uniform: some of them are large brick buildings with flat roofs, but the greater part are built of mud, with tiled roofs. It makes a better appearance from a distance than when it is closely inspected. The Black Town is the residence of the native Armenian and Portuguese merchants, and also of many European settlers not the servants of the Company.

In Lord Valentia's account of Madras, it is observed, that it would probably have been difficult to find a worse place for a capital than that chosen for Madras, on the extreme point of a coast where the current is most rapid, and where a tremendous surf breaks even in the finest weather. But the original error of fixing on this for the site of a great capital cannot now be recalled, the expense of removal to a more convenient spot would be so great. Owing to the exposed situation of Madras, it affords no secure anchorage; and there is always a great difficulty in landing from vessels, which generally moor in nine fathoms, with the flag-staff west-north-west, about two miles from the shore. Any ship's boat that should attempt to cross the surf would inevitably perish; and, accordingly, the boats from ships anchor outside the broken water, and wait for the country boats to carry the passengers safely to the shore. These boats are of a particular construction, being built of soft wood, with flat bottoms. They are sewed together, and have not a nail in their whole construction, so that they are very light and pliable, and are borne many yards through the surf without injury, as they yield to the waves like leather. These boats require to be guided by seamen of experience and tried skill, and it is an extremely critical operation to conduct them through the surf. When they come within its influence, the cockswain stands up, and, under great agitation, marks time with his voice and his foot, whilst the rowers work their oars backwards until overtaken by the swell, which, curling up in its approach to the shore, sweeps the boat along with fearful violence. The rowers now ply every oar forward with their utmost vigour, to prevent the wave from carrying back the boat with its receding swell; and by a few successive surfs the boat is at length dashed high and dry on the shore. A species of floating machine called a catamaran, formed of two or three light logs of wood, eight or ten feet in length, lashed together with a small piece of wood inserted between them to serve as a stem-piece, is employed by the fishermen and lower classes of natives to carry them through the breakers. On these they go out to fish, or to carry letters or small quantities of refreshments to ships when no boats can venture out. They secure the letters in a pointed cap, where they cannot be damaged; and when the men happen to be washed off by the surf, they regain the catamarans by swimming, unless when they are attacked by a shark. The dexterous navigators of these frail vessels who distinguish themselves by saving persons in danger, or by their care in conveying papers through the surf in dangerous weather, are rewarded with medals.

Madras, when seen from the sea, presents a striking appearance, the fortifications of Fort St George being within a few yards of the shore; and, at a distance, minarets and pagodas are seen mixed with trees and gardens. The public offices and storehouses are fine buildings, with colonnades to the upper stories, supported on arched bases, covered with beautiful shell-mortar from Madras, which is hard, smooth, and polished. These being near the beach, which is always crowded, form interesting objects. At a distance, the low, flat, sandy shores extending to the north and south, and the small hills that are seen inland, give an appearance of barrenness, which, however, improves on a closer inspection. Madras is surrounded by a level country, which in general exhibits a naked, brown, dusty plain, with few villages to enliven the scene, or any other objects to relieve the eye, except a range of abrupt detached hills to the south. The huts of the natives are covered with tiles, and are fully superior in their appearance to those in Bengal; and in the inns and chaultries, also, which are common on the roads, travellers experience greater attention. The soil in the vicinity of Madras is very poor, and formerly provisions were scarce and dear; but since the great accession of territory that has accrued to the Madras presidency, they are brought from the Barramahal and other parts of the country in great abundance. The soil, however, when it is cultivated, and where there is abundance of water, produces a good crop of rice; and artificial irrigation often makes up for natural disadvantages. The cattle that are found in the neighbourhood of Madras are a small breed, such as are commonly seen in the Deccan; but they are larger than those in the southern parts of Bengal. Buffaloes of a small size are generally used in carts.

The manners of the Europeans at Madras, the state of society, and style of living, are nearly the same as in other parts of India, except that provisions are more expensive. Within doors, dinner parties, and, during the cold season, monthly assemblies and balls, constitute the routine of amusements. Amongst the public places of resort is the Mount Road, leading from the fort to St Thomas's Mount, which is quite smooth, and embellished on each side with banyan and yellow tulip trees. Here it is customary for the fashionable parties in Madras to repair, in their gayest equipages, during the cool of the evening, where they drive slowly about the cenotaph which is here erected to the memory of Marquis Cornwallis, and converse together. During the hottest part of the day, namely, after two o'clock, which is the time when tiffin or the real dinner is eaten, many retire to rest until five o'clock, when the master of the family returns from the fort, and an excursion to the Mount Road, and dinner, then occupies the remainder of the day, unless it be prolonged by a ball and supper in the evening. The morning, from nine to eleven, is the time for visiting, when the European residents call on each other, retail the news, and offer their services to their friends in the city, to which they must repair for purposes of business. Another tribe of visitors succeeds, and thus the forenoon passes away.

European passengers, when they land at Madras, being ignorant of the language, manners, and customs of the country, necessarily rely on the natives for help; and, accordingly, passengers landing at Madras are immediately surrounded by numerous servants of all kinds, called dobashies, eager for employment. They undertake to transact for the Europeans all their necessary business, to buy all that is wanted, and to procure servants, tradesmen, palanquins, and the like. They are of different castes, according to the nature of the duties which they undertake to perform.

Madras carries on a very considerable trade, not only with Europe, but with China, Ceylon, Pegu, the Isle of France, New Holland, and different parts of India. But, owing to the want of a navigable river, and the difficulty of landing goods, it labours under great disadvantages, and its commerce is inferior to that of the other two presidencies. From America the imports are some inferior sorts of wines, spirits, and provisions. Rice is imported from Bengal, also raw silk, canvass, piece goods, muslins, and shawls of a coarse description, silk piece goods of an inferior kind, long pepper, sugar, borax, saltpetre, precious stones, &c. From Bombay are imported, through the Persian and Arabian Gulfs, dried fruit or drugs, cotton and other goods; from Ceylon, biche de mer, shark fins, ebony, &c. also pearls; from China, tea, sugar, nankeen, China ware, with alum, camphor, drugs, piece goods, stationery, &c.; from Manilla, indigo; from the Isle of France, brandy, copper, iron, lead, &c.; from Pegu, the staple article is timber; from the Malabar coast, pepper, timber, coir, cordage, &c.; from London, different articles of European manufacture, in glass, iron, copper, tin, and other manufactures, also supplies of wine and other necessaries; from Madeira, wine. The exports of Madras consist of piece goods to America; to Batavia, piece goods of a coarse coloured sort, handkerchiefs, and a proportion of southern blue cloths; to Bengal, some red wood, coloured piece goods, and salt; to Bombay, chintz and coloured turbans to an inconsiderable amount; to Ceylon, principally European and China articles; to China, principally cotton; to Manilla, piece goods, namely, cambays, handkerchiefs, &c.; to the Isle of France, chiefly long cloths, handkerchiefs, muslins, ginghams, &c.; to Pegu, coarse handkerchiefs, and copper, arrack, brandy, mace, cloves, iron, glass ware, naval stores, &c. which are re-exported. It does not appear that the trade of Madras, which is really the trade of the coast of Coromandel, is increasing. For this several causes are assigned. Amongst these are various oppressive inland taxes, which obstruct the progress of improvement. Owing to the former monopoly of the East India Company, the raw silks and nankeens of China, which could not be exported directly to Europe, were brought to Madras, and thence re-exported. They are now directly exported from Canton, and the trade is consequently lost to Madras. The value of the exports and imports of Madras, in bullion and merchandise, was in 1813–14 L.695,373, and in 1828–29 L.788,959, thus exhibiting during this interval only the trifling increase of L.93,586.

Considerable variety of coin circulates in Madras and its vicinity. Of the gold coins, the principal are, star or current pagodas, value 7s. 5½d. or 8s. The gold rupee, new coinage, is worth L.1. 9s. 2d. The Arcot rupee, and the new silver rupee, are worth 1s. 11½d., and 1s. 11⅓d. The accounts are kept in star pagodas, fanams, and cash; eighty cash make one fanam, twelve fanams one rupee, and forty-two fanams a star pagoda. The natives keep their accounts at twelve fanams sixty cash to a rupee, and forty-four fanams sixty cash to a pagoda. The current coins consist of various sorts of pagodas, Arcot rupees, single and double fanams, and copper coins of twenty, ten, five, and one cash each, called dodees and half dodees.

The English possessed no fixed establishment here until A. D. 1639, when they received a grant from the Hindu dynasty of Bijanagur, then reigning at Chandergherry, permitting the erection of a fort. In consequence of this permission, Mr Day proceeded with great alacrity to the construction of a fortress, which in India is soon surrounded by a town; and this town he allowed to retain its Indian appellation, but the fort he named Fort George. The territory granted along with it extended five miles along shore, and one mile inland. For about a century, Madras, with the small portion of territory adjoining, continued to be held by the Europeans, but rather under, or at least with the consent of, the native powers, than as an independent colony. On the 12th of December 1687, the population of the city of Madras, Fort George, and the villages within the Company's bounds, was estimated to amount to 300,000 persons. In 1744 Madras was besieged by the French from the Mauritius under M. de la Bourdonnais, at which period the native inhabitants within the Company's territory amounted to 250,000. The English in the colony did not exceed 300, and of these 200 only were soldiers of the garrison. The town was taken on the 10th of September, and was ransomed for L.440,000, besides plunder to the amount of L.200,000 more. All the British inhabitants were afterwards compelled to abandon the place. Madras was restored at the peace of Aix-la-Chapelle, and evacuated by the French in August 1749, when it was found in a very improved condition, the bastions and batteries having been greatly enlarged and strengthened. The defences of the town were still, however, inferior to those of Fort St David, where the East India Company ordered the presidency to continue. Madras was again besieged in 1758, by the French under M. Lally. The siege commenced on the 17th of December 1758, and was prosecuted with vigour till the 17th of February, when the French were obliged precipitately to raise it. This was the last and most memorable siege which Madras ever sustained. The garrison consisted of 1758 European troops, 2200 sepoys, and 150 European inhabitants. The besieging force consisted of 3500 Europeans, 2000 sepoys, and 2000 native and European cavalry. Since this period Madras has never been assailed by an enemy, though nearly approached by Hyder's cavalry in 1781, when they descended from the mountains to ravage the plains of the Carnatic. The population of the city of Madras, Fort George, and the villages within the Company's bounds, is 300,000. Long. 80. 25. E. Lat. 13. 5. N. (Lord Valentia's *Travels;* Rennell's *Memoir;* Hamilton, &c.)

The presidency of Fort George, or of Madras, comprehends nearly the whole of India south of the Krishna River, and also that large portion of the Deccan, the Northern Circars. Within these boundaries there are three independent princes, namely, the rajahs of Mysore, Travancore, and Cochin, who, though subject to the Company in external politics, are left free to manage their own internal concerns. The rest of the country is under the immediate jurisdiction of the governor and council of Madras, and, for the collection of the revenue and the administration of justice, is divided into the following districts, namely,—

The Northern Circars.	1. Ganjam.	
	2. Vizagapatam.	
	3. Rajamundry.	
	4. Masulipatam.	
	5. Guntoor, including Palnaud, which is part of the Carnatic.	
Carnatic.	6. Nellore and Ongole, including part of the Western Pollams or Zemindaries.	
	7. Northern division of Arcot, including Sativaid, Pullicat, Coongoody in the Barramahal, part of Ballaghaut, and the Western Pollams or Zemindaries.	
	8. Chingleput, or the Jaghire.	
	9. Southern division of Arcot, including Cuddalore and Pondicherry.	
	10. Trichinopoly.	
	11. Tanjore.	
Mysore and Carnatic.	12. Dindigul, including Madura, Manapara Pollams, Ramnad, and Shevagunga, forming part of the Southern Carnatic.	
Southern Carnatic.	13. Tinevelly.	
Mysore.	14. Bellary	Balaghaut ceded districts.
	15. Cudapah	
	16. Seringapatam.	
	17. Salem and Kistnagherry.	
	18. Coimbetoor.	
	19. Canara.	
	20. Malabar.	
	21. Madras.	

A full account of these provinces, of the land revenue, the administration of justice, and other details of the same nature, is given under the article HINDUSTAN; also under the articles CANARA, MALABAR, CIRCARS NORTHERN, and the names of the districts into which the presidency is divided. (F.)

MADRID, the metropolis of the Spanish empire, and also the capital of a province of the same name, in the centre of Spain, being about 300 miles from the sea in each direction. The province includes the city, and about two hundred villages that surround it. The ground on which these several villages are built is so uneven in its surface, and has so many valleys and hills, that scarcely more than three or four of them are visible from the same point. The extent of the province is 110 square leagues, and the number of inhabitants is 228,520, including 168,000 who reside within the city.

The city of Madrid is of modern erection, and is consequently not so Gothic in appearance as the other cities of the Peninsula. Though the ground on which it stands is irregular, the streets are laid out with great judgment, well paved, and have convenient footpaths, with broad stones. The city is well supplied with water from several public fountains, and, having been filtered by passing seven or eight leagues over beds of gravel or sand, it is remarkable for its great purity. The principal square, a pile distinguished by its extent and its beauty, is in north latitude 40. 25. 7. In this square and in the other markets, notwithstanding the natural sterility of the province, an abundant supply is at all times to be seen of excellent bread, of fruits, of horticultural vegetables, of fish, of poultry, and of butcher-meat.

Madrid, though deemed a cold situation by the natives of the other towns of Spain, does in reality enjoy an equable and temperate climate. With the exception of a short period, when the dry winds from the north blow cold, and a few days in the very midst of summer, when it is intensely hot, a great degree of equality of temperature prevails. In the greatest heat the centigrade thermometer is seen at 40°, and in the cold weather it is 8° 5′. The medium heat of the year is 14° 0′ 35″ above zero. The medium height of the barometer is thirty inches and a third. Its height above the level of the sea, according to the formula of Laplace, by observations of the medium height of the barometer and thermometer at Madrid and on the coast, is 2170 English feet. It may be said, that all the circumstances which contribute to communicate salubrity to a city are found in Madrid, and hence the inhabitants enjoy as much health and longevity as are experienced by the people of any large city in Europe; nor has it ever been visited by contagious fevers.

The roads in the vicinity of Madrid are generally in a bad state; those called *caminas reales* are good, but they lead only in a few directions, and the other roads are miserably neglected. The way from the north is over some prodigious mountains, which must be passed before reaching the capital. One of the highest points of the mountains of Guadarama is 4580 feet above the level of the sea, and the extensive plains of New Castille may be seen from its summit, to the greatest extent of the powers of vision.

The whole of the city is on the left bank of the Manza-nares, a river whose waters are in general far from copious, but over which two magnificent bridges have been constructed. On its banks there are some large trees; and its waters irrigate some gardens, which are fruitful, and adjoin a royal residence, or rather retreat, called Casa de Campo. Around the city, near the river, wheat and barley are cultivated, with the assistance that the manure of a large town yields. The produce of wheat is from nine to twelve for one, and of barley from fourteen to sixteen for one, on the quantity sown. The soil is better adapted for vines, though but few are cultivated, and these rather for the table than for making wines.

There is no episcopal church in Madrid; and the other churches, though, like all in Spain, they are costly and large, do not rise so high above the common level as to attract any very particular notice. They are seventy-seven in number, and there are also seventy-five monasteries. The most magnificent pile of building in Madrid is the royal palace, built after the destruction of the former by fire in 1734. The ceilings of the palace are painted by the most eminent artists of the period, Mengs, Corrado, and Tiepolo. The richest marbles, all from Spanish quarries, are used in the floors, the cornices, and the door and window frames. The great chamber of audience is remarkably splendid, the walls are covered with beautiful marbles, hung with plate-glasses of the largest size. The ceiling, painted with allegorical history, and the cornices with figures of the different people under the Spanish crown, is admirably executed. This palace is, or rather was before the French entered it, adorned with a fine collection of pictures from the hands of the first masters. Some of the best productions of Titian, Reubens, Vandyke, Murillo, Velasquez, Spagnoletti, Mengs, and other masters, decorated this edifice. With all its magnificence, this palace is in a bad situation, and has never been the favourite residence of any of the monarchs except the original founder. Few places of equal extent have so small a number of objects to attract the notice of casual strangers as the city of Madrid. Though many of the public buildings are grand, there are none of them of such superiority as to draw great admiration from observers. The public walks are handsome and much frequented, and the gardens of the royal residence, called Buen-Retiro, are opened for the public recreations, and are highly delightful. The Puerto de Sol, and some of the other entrances, have gates that display taste in architecture, and excite admiration in travellers. There is but little commerce in Madrid, and few manufactories; the establishments by the government for making saltpetre, porcelain, brandy, cards, and tapestry, have never flourished, and are now very much reduced. As the nobility of Spain seldom reside on their domains, but attach themselves to the court, a considerable number of them are collected here, and spend their revenues: this class, with the officers of government, the members of the different boards of administration, the members of the profession of the law, the clergy, and the military, with their dependents and tradesmen, compose the great mass of the population of Madrid.

The king of Spain is an absolute monarch, and issues his orders to the different boards of administration, who put them in execution. They are, the council of Castille, the council of the Indies, the junta for the administration of justice and political affairs, the tribunal of revenues, the council of war and naval affairs, the inquisition for matters of faith, and the junta for the final decision of controversies in ecclesiastical affairs. The tribunals of justice are in Madrid; but the high tribunals in the provincial capitals decide on almost every case, without appeal being made to the court in Madrid. There are several literary institutions, which, though not of extensive influence beyond the capital, are both useful and respectable. There are four academies, one for the Spanish language, one for history, one for the arts and sciences, and one for medicine and natural history. There is a very respectable learned body, the *Sociedad Economica*, which has corresponding branches in sixty-one towns of the kingdom, established with the intention of diffusing the knowledge of political economy, and promoting the advancement of the useful arts. The royal library, always open to public inspection and use, contains upwards of 130,000 volumes of printed books, besides manuscripts, and a rich collection of medals. See the article LIBRARIES.

There is a seminary established by the government for the education of the nobility, just without the city, which is a most splendid and capacious building, and liberally, if not learnedly, supported. There are in the city no less than nineteen hospitals, and several infirmaries, to which the sick of all classes and of every country are freely admitted. The autumnal season is, of all others, that in which Madrid is, if not the most healthy, yet, on the whole, the most agreeable residence. This city was the birthplace of the poet Lopez de la Vega, in 1635; of Francisco de Quevedo Villegas, in 1647; and of Monso de Erzilla, in 1590.

MADRIGAL, a short, amorous poem, composed of a number of free and unequal verses, neither confined to the regularity of a sonnet, nor to the point or antithesis of an epigram, but only consisting of some tender and delicate thought, expressed with a beautiful, noble, or elegant simplicity. Ménage derives the word from *mandra*, which, in Latin and Greek, signifies a sheep-fold; imagining that it had been originally a kind of pastoral or shepherd's song, whence the Italians formed their *madrigale*, and the English *madrigal*. But others derive it from the word *madrugar*, which in the Spanish language signifies to rise in the morning; the *madrigales* having been formerly sung early in the morning by those who had a mind to serenade their mistresses.

MADRILEJOS, a small town of Spain, in the province of New Castille, upon a range of mountains that run between the rivers Guadiana and Tagus. It stands in a very bleak situation, and on a very sterile soil.

MADURA, an extensive district of Hindustan, in the Southern Carnatic, situated chiefly between the ninth and tenth degrees of north latitude. It was annexed in 1742 to the dominions of the nabob of the Carnatic, and in 1801 came into the possession of the British. It is bounded on the north by the Polygar territory and Dindigul, on the south by Tinevelly, on the east by the district of Marawas, and on the west by that of Dindigul. The Vaygaroo and Candaroo are the chief rivers, and the principal owns Madura and Scholavanden. It has a tolerably fertile soil, and is well supplied with water; but its cultivation has always been inferior to that of Tanjore, which was probably owing to the warlike habits of the Zemindars and Polygars, living in castles surrounded with woods, in a constant state of war with each other. The name of the capital is Madura, which is an ancient city of the Southern Carnatic, the four sides of which front nearly the four cardinal points. It was formerly well fortified with a ditch, rampart, and square towers, and from 1740 to 1760 sustained many sieges, and was often in possession of refractory Polygars. Since it has come into the possession of the British, the peace of the country has been firmly maintained, so that it is now quite superfluous to keep up this or any other fortress. The travelling distance from Seringapatam is 240 miles, and from Madras 307 miles. Long. 78. 13. E. Lat. 9. 51. N.

MADURA, an island in the Eastern Seas, situated off the north coast of the island of Java, from which it is separated by the Strait of Madura, which is a hundred miles in length by sixteen in average breadth. The channel at its narrowest part is only eighty-three fathoms wide, and is marked by buoys. There is a depth of only three fathoms at the entrance, which can easily be passed by ships of a large size, the bottom being of a soft mud, through which a vessel is carried by the slightest breeze, aided by the current, which is strong. The inhabitants resemble the Hindus in their appearance, and worship their divinities, namely, Indra, Surya, and Vishnu. The inhabitants of the interior are rude and barbarous. They attack their enemies with poisoned arrows, which they blow through a tube. The Dutch invaded and subdued this island in 1747, and made slaves of a great number of them. Long. 112. 54. E. Lat. 6. 44. to 7. 15. S.

MÆANDER, in *Ancient Geography*, a celebrated river of Asia Minor, rising near Celænæ. It flows through Caria and Ionia into the Ægean Sea between Miletus and Priene, after having been increased by the waters of the Marsyas, Lycus, Eudon, Lethæus, and other tributaries. It is celebrated amongst the poets for its windings, which amount to no less than six hundred, and from which all recurring sinuosities have received the name of *mæanders*.

MÆATÆ, anciently a people of Britain, near the wall of Severus, inhabiting the district now called *Lauderdale*, in Scotland.

MÆCENAS, Caius Cilnius, the friend and counsellor of Augustus Cæsar, a man whose name has become a synonyme for a patron of literature, from the munificent and generous support he afforded to the learned. He flourished from about 41 to 8 B. C. He was very generally considered by the ancients as descended from the royal line of Etruria. The family of the Cilnii is mentioned by Livy (x. 3) as very powerful at Arretium, now Arrezzo, B. C. 300. We have no account of the early years of Mæcenas, but there is little doubt that his education was carefully attended to, and becoming the dignity of his birth. In what way he acquired the friendship of Octavius we have no means of knowing; but we find him actively engaged in his cause immediately after the murder of Julius Cæsar, B. C. 44. His talents seem to have been particularly adapted for the administration of the civil affairs of government, and we find him more frequently thus engaged than in the active business of war. He was employed (B. C. 40) to negociate the marriage between Augustus and Scribonia, the sister of Scribonius Libo, the father-in-law of Sextus Pompey, with the view of securing a channel by which he might obtain peace with Pompey if circumstances should require it (Appian. *B. C.* v. 53). The same year Mæcenas was one of the commissioners appointed to negociate the peace between Antony and Octavius at Brundusium, which was sealed by the marriage of Octavia and Antony (v. 64). He was again the principal person employed in the conference between Octavius and Antony (B. C. 37), on the banks of the river between Metapontum and Tarentum, when peace was agreed upon (v. 92). He had the command of the whole of Italy and Rome at the time of the battle of Actium, B. C. 31, at which period he put down a conspiracy entered into by Lepidus the son of the triumvir (iv. 50; Vell. Pat. ii. 88). The victory at Actium having placed the Roman empire in the hands of Octavius, he consulted with his friends, Agrippa and Mæcenas, whether he ought not to abdicate his authority. Agrippa advised him to restore the republic, but Mæcenas was of a contrary opinion. The speeches which they each delivered are given by Dion Cassius (411, 1–40). Augustus adopted the opinion of Mæcenas, and was guided in all his more important transactions by his advice, having confidence not only in his good sense and discretion, but in the integrity of his character. To Mæcenas therefore may, in a great measure, be ascribed the glory of his reign. After his death, Augustus frequently regretted that he had no longer a friend to assist him; and when he had committed any act of which he repented, he used to say, that if Mæcenas or Agrippa had been alive, he would not have had cause to reproach himself for the folly of his conduct (Sen. *De Benef.* vi. 32). It is said that Mæcenas one day observed Augustus on the point of condemning some persons to death, and being unable to approach the tribunal on account of the crowd, he threw a paper to him, on which he had inscribed these words, "Descend from the tribunal, thou butcher;" upon which Augustus, struck by the admonition, left the judgment-seat without passing sentence. The palace of Mæcenas was on the Esquiline Hill, and his gardens are frequently mentioned as occupying the ground which had been previously employed as the place of burial for the poor (Tacit. *Ann.* xv. 39). It is, however, to his generous patronage of the learned that he is principally indebted for his fame; and their gratitude has amply repaid all the attention he may have bestowed on them. His palace was the common resort of all the literary characters of his age. There might be found Virgil and Horace, Varius, famed for his tragedies, Propertius, Domitius Marsus the rival of Catullus, Valgius, Plotius, and Tucca. It was through Mæcenas that the learned had access to the emperor, and were loaded with his favours. Horace gives a very interesting account of his introduction to Mæcenas, which must have taken place as early as B. C. 40, when both the poet and Mæcenas were still young. To Mæcenas Horace was indebted for his Sabine farm; and Virgil was through him restored to his paternal estate, near Mantua. Virgil dedicated the Georgics to his patron; and to him Propertius has dedicated several of his poems. It is needless to add, that much of the poetry of Horace was also addressed to him. Mæcenas has been accused, however, of being devoted to pleasure; but his faults were those of the age in which he lived, and his virtues were his own (Senec. *Epist.* 92, 114). Virgil died many years before Mæcenas, B. C. 19; but whether Horace predeceased Mæcenas or not is uncertain. Horace died in the month of November B. C. 8 (Sueton.); and Dion Cassius (41, 3) mentions the death of Mæcenas towards the close of the same year. The clause in the will of Mæcenas, in which he recommends to Augustus his friend Horace, would lead us to conclude that Horace survived him. At all events, only a few months could have intervened between their deaths. He was married to Terentia, a woman of a disagreeable temper, from whom he frequently separated; but found his happiness so dependent on her smiles, that he soon received her back to his arms (Sen. *De Prov.* 3). Pliny states that the health of Mæcenas was at all times delicate; and that for the last three years of his life he scarcely enjoyed an hour's sleep (vii. 52, 2). Of the writings of Mæcenas we have nothing remaining except a few epigrams, which are published in the *Anthologia Latina* of Burmann (i. 53, ii. 225, iii. 149). He was also the author of two tragedies, Prometheus and Octavia; and is supposed to have written Memoirs to serve for the history of Augustus. (See Fabricius, *Bibliotheca Latina*, iii. 964; *De Mæcenatis Vitâ, Moribus, et Rebus Gestis*, auct. Meibom. Lugd. Bat. 1653; Lion, *Mæcenatiana*, Götting. 1824; *Mémoires de l'Acad. des Inscrip.* xiii.)

MAELSTROM, a dangerous whirlpool on the coast of Norway, in the sixty-eighth degree of latitude, in the province of Nordland and the district of Lofoden, and near the island of Moskoe, whence it also takes the name of *Moskoe-ström*. Its violence and noise exceed that of a cataract, being heard at a great distance, and without any intermission, except a quarter every sixth hour, that is, at the turn of high and low water, when its impetuosity seems checked; and this short interval is the only time during which the fishermen can venture in: but the motion soon returns, and, however calm the sea may be, gradually in-

Magazine.

creases, with such a draught and vortex, as to absorb whatever comes within its sphere of action, and keep it under water for some hours, when the fragments, shivered by the rocks, again appear.

MÆMACTERIA, sacrifices offered to Jupiter at Athens in the winter month Mæmacterion, when the god surnamed Mæmactes was entreated to send mild and temperate weather, as he presided over the seasons, and was the god of the air.

MÆMACTERION was the fourth month of the Athenian year, containing twenty-nine days, and answering to the latter part of our September and the beginning of October. It received its name from the festival *Mæmacteria*, which was observed about this time. This month was called by the Bœotians *Alalcomenius.*

MÆONIA, a country of Asia Minor, and forming part of Lydia, being in the neighbourhood of Mount Tmolus, and the country watered by the Pactolus. The rest on the sea-coast was called Lydia.

MÆONIDÆ, a name given to the muses, because Homer, their greatest and worthiest favourite, was supposed to be a native of Mæonia.

MÆONIDES, a surname of Homer, because, according to the opinion of some writers, he was born in Mæonia, or because his father's name was Mæon.

MÆOTIS PALUS or LACUS, *Mæotica Palus*, or *Mæoticus Lacus*, in *Ancient Geography*, a large lake, or part of the sea, between Europe and Asia, at the northern extremity of the Euxine, with which it communicates by the Cimmerian Bosphorus. It was worshipped as a deity by the Massagetæ. It extends about 390 miles from south-west to north-east, and is about 600 miles in circumference. The *Palus Mæotis*, or Sea of Azof, reaches from the Crimea to the mouth of the Don.

MAESNIEL, a town of the Netherlands, in the province of Limburg, and arrondissement of Roermonde. It contains 200 houses and 1180 inhabitants.

MÆSTLIN, MICHAEL, in Latin *Mæstlinus*, a celebrated astronomer of Germany, was born in the duchy of Wittemberg, but spent his youth in Italy. He made a speech in favour of Copernicus's system, which is supposed to have brought over Galileo from Aristotle and Ptolemy, to whom he had been hitherto entirely devoted. He afterwards returned to Germany, and became professor of mathematics at Tubingen, where, amongst his scholars, he taught Kepler, who has praised several of his ingenious inventions in his *Astronomia Optica.* Though Tycho Brahe did not assent to Mæstlin's opinion, yet he allowed him to be an extraordinary person, and deeply skilled in the science of astronomy. Mæstlin published many mathematical and astronomical works, and died in 1590.

MAESTRICHT, a city of the Netherlands, in the province of Limburg, of which it is the capital, as well as of the arrondissement of the same name. It is situated on the left side of the river Meuse, over which is a stone bridge 500 feet in length, connecting it with the suburb Wyk. It is one of the strongest as well as one of the most extensive fortifications in Europe, including in it the citadel of Petersburg. It is well built, has a fine place or square, eight churches, three hospitals, and an orphan-house. It contains 3000 houses, and 19,500 inhabitants. The chief commerce is that which arises from the river, by which the stone is conveyed to Holland, as well as the coal and iron from Liège. There are some breweries and distilleries, and some small manufactures of common articles. Long. 5. 35. 41. E. Lat. 50. 51. 7. N.

MAFFÆUS, VEGIO, a Latin poet, born in Lombardy in 1407, was greatly admired in his time. He wrote epigrams, and a humorous supplement to Virgil, which he called the thirteenth book of the Æneid, and which has been translated into English by Mr Ellis. Maffæus also wrote some prose works. He was chancellor of Rome towards the end of the pontificate of Martin V., and died in 1458.

MAFFEI, SCIPIO, a celebrated Italian poet, descended of an ancient and illustrious family at Verona, was born in 1675. After having finished his studies, he took arms, and distinguished himself by his valour at the battle of Donawert; but he more particularly signalized himself by his love of learning, which made him undertake several journeys into France, England, and Germany. He conversed with the learned in all these countries, and obtained their friendship and esteem. He was a member of the academy of the Arcadians at Rome, an honorary foreign member of that of Inscriptions at Paris, and died in 1755. He wrote many works in verse and prose, which are esteemed. Of these, the best known are, 1. The Tragedy of Merope, of which there are two French translations in prose; 2. Ceremony, a comedy; 3. A Translation, into Italian verse, of the first book of Homer's Iliad; 4. Many other pieces of poetry, in a collection entitled *Rhyme and Prose*, 4to. His principal works in prose are, 1. Verona Illustrata; 2. Istoria Diplomatica; 3. Scienza Cavalleresca, an excellent work, in which he attacks duelling; 4. An edition of the Theatro Italiano; 5. An edition of Cassiodorus on the Epistles, Acts of the Apostles, and Apocalypse; and, 6. Galliæ Antiquitates quædam selectæ, atque in plures Epistolas distributæ; besides several other works.

MAFRA, a small town in Portugal, the principal celebrity of which is derived from a royal convent, one of the most splendid in the kingdom. The convent contains three hundred cells, for as many monks. The church, which is in the centre, is large and handsome; and the marble steps leading to it are peculiarly grand. The interior is ornamented with beautiful marbles, exquisitely wrought. There are in it six organs and twelve altars. The whole pile is enormous, being two hundred and sixty feet in length, containing eight hundred and seventy apartments, and five thousand two hundred windows. Near the convent is an extensive and beautiful royal park, well stocked with game of every kind. It is in the province of Estremadura, and contains 1000 inhabitants.

MAGADA, in *Mythology*, a title under which Venus was known and worshipped in Lower Saxony, where this goddess had a famous temple, which was treated with respect even by the Huns and Vandals when they ravaged the country. It is said to have been destroyed by Charlemagne.

MAGAS, MAGADIS (from μαγαδιζειν, *to sing or play in unison*), the name of a musical instrument in use amongst the ancients. There were two kinds of *magades*, the one a stringed instrument, formed of twenty chords arranged in pairs, and tuned to unison, so that they yielded ten sounds; the invention of which is ascribed by some to Sappho, by others to the Lydians, and by others to Timotheus of Miletus. The other was a kind of flute, which at the same time yielded very high and very low notes. The former kind was much improved by Timotheus of Miletus, who is said to have been impeached of a crime, because, by increasing the number of chords, he spoiled and discredited the ancient music.

MAGAZINE, a place in which stores are kept, of arms, ammunition, provisions, and the like.

Powder MAGAZINE is that place where gunpowder is kept in large quantities. The first powder magazines were made with Gothic arches; but Vauban finding them too weak, constructed them in a semicircular form. Their usual dimensions are sixty feet long within, and twenty-five broad; the foundations are eight or nine feet thick, and eight feet high from the foundation to the spring of the arch; and the floor is two feet from the ground, which secures it from dampness.

Artillery MAGAZINE. In a siege, the magazine is made about twenty-five or thirty yards behind the battery, towards the parallels, and at least three feet under ground, to contain the powder, loaded shells, portfires, and the like.

MAGAZINE, on shipboard, a close room or storehouse, built in the fore or after part of the hold, to contain the gunpowder used in battle. This apartment is strongly secured against fire, and no person is allowed to enter it with a lamp or candle; it is therefore lighted, as occasion requires, by means of the candles or lamps in the *light-room* contiguous to it.

MAGAZINE, Literary, a well-known species of periodical publications. One of the first that appeared was *The Gentleman's Magazine*, set on foot by Mr Edward Cave, in the year 1731. This, as Dr Kippis observes,[1] "may be considered as something of an epocha in the literary history of this country. The periodical performances before that time were almost wholly confined to political transactions, and to foreign and domestic occurrences; but the monthly magazines have opened a way for every kind of inquiry and information. The intelligence and discussion contained in them are very extensive and various; and they have been the means of diffusing a general habit of reading through the nation, which, in a certain degree, hath enlarged the public understanding. Many young authors, who have afterwards risen to considerable eminence in the literary world, have here made their first attempts in composition. Here too are preserved a multitude of curious and useful hints, observations, and facts, which otherwise might have never appeared; or, if they had appeared in a more evanescent form, would have incurred the danger of being lost."

MAGDALEN, MARY. See MARY.

Religious of St MAGDALEN, a denomination given to different communities of nuns, consisting generally of penitent courtezans, sometimes also called *Magdalenettes*. Such were those at Metz, established in 1452; those at Paris, in 1492; those at Naples, first established in 1324, and endowed by Queen Sancha, to serve as a retreat for public courtezans, who should betake themselves to repentance; and those of Rouen and Bordeaux, which had their origin amongst those of Paris in 1618. In each of these monasteries there are three kinds of persons and congregations; the first consists of those who are admitted to make vows, and these bear the name of *St Magdalen;* the second is the congregation of St Martha, composed of those whom it is not judged proper to admit to vows; and the third is the congregation of St Lazarus, composed of such as are detained there by force. The religious of St Magdalen at Rome were established by Pope Leo X. Clement VIII. settled a revenue on them, and further appointed that the effects of all public prostitutes dying intestate should fall to them, and that the testaments of the rest should be invalid unless they bequeathed to them a portion of their effects, amounting at least to a fifth part.

MAGDALENA, one of the Marquesas Islands, about five leagues in circumference, and supposed to be in south latitude 10. 25. and west longitude 138. 50. It was only seen at nine leagues distance by those who discovered it.

MAGDEBURG, a government of the Prussian province of Saxony, formed out of the ancient duchy of that name, of the county of Barby, and of all the bailiwick of Gommern except the circle of the Saal; but the principalities of Halberstadt, of Derenburg, of Quedlingburg, of Wernigerode, and of Schauen, are included within it. It extends over 4489 square miles, and comprehends fifty cities or towns once walled, three market-towns, and 1497 villages and hamlets, containing a population (in 1826) of 526,197 persons. It is divided into fifteen circles, one of which, of the same name, contains the capital of the government. The city of Magdeburg is situated on a rising ground, on the left bank of the river Elbe. It is very strongly fortified on the south side by strong lines, with ditches and sixteen bastions, and by two forts; on the north, the river is a defence, as well as the marshes beyond it, and several powerful outworks. There is a bridge leading to the citadel, which is built on an island formed by one of the branches of the Elbe. The walls are of great thickness, and though the ditches on the land side are dry, they are all undermined. The city is built in the old Saxon style, with large massive houses, and, with the exception of the high street, narrow lanes. There are, however, two good open places, the old market and the cathedral place. Some of the public buildings are magnificent, particularly the government-house and the Domkish, the latter of which has a tower 330 feet high, which has survived the destruction that visited the city when it was stormed, plundered, and burned by the imperial army under Tilly, in the Thirty Years' War. It contains now sixteen churches, ten of which are Lutheran, the others Catholic, Calvinist, or Menonite. It is a place of great commercial as well as manufacturing industry. Its situation on the Elbe connects it with the sea, through Hamburg and the upper parts of the river, including Prussia. Saxony, and a part of Bohemia, receive their foreign productions by this channel. The goods made in Magdeburg are of linen, cotton, and woollen, hats, hosiery, corn, spirits, leather, soap, and tobacco and snuff. The fields around it are fertile, and the government is the corn granary of Prussia; and large quantities of tobacco are grown. The city and suburbs contain 52,000 inhabitants, exclusive of military. Long. 11. 33. 25. E. Lat. 52. 8. 4. N.

MAGEBOE, a large island in the northern part of Norwegian Lapland. It is a rocky spot, with a few valleys, in which pasture is found sufficient to maintain a few families, who have some cows, and a small number of sheep, and about 600 rein-deer. The winter is dreadfully severe, and the ground is covered with snow to the depth of twelve or fourteen feet. It is in long. 26. 45. E. and lat. 71. 30. N.

MAGELLAN, or MAGELHAENS, FERDINAND DE, an eminent navigator, was by birth a Portuguese, and of a good family. He served with reputation in the East Indies for five years under Albuquerque, and in 1510 he greatly distinguished himself at the battle of Malacca. Deeming his services poorly repaid by his own court, he entered into the employment of Charles V. king of Spain. He has been charged with peculation by some of his countrymen, who assign this as the reason why he quitted Portugal. In conjunction with Ruy Folero he formed the bold design of discovering a new passage by the west to the Molucca Islands, which, he offered to prove, fell within the division of the globe assigned by the pope to the crown of Castille. It is said that he first proposed this enterprise to Emanuel king of Portugal, who rejected it, as opening a way for other nations to have access to the East Indies, the trade of which was then monopolized by the Portuguese. The proposition was agreed to by the king of Spain, and, on the 20th of September 1519, Magellan sailed from San Lucar, with five ships and 236 men under his command. His officers soon murmured at this appointment, considering it as a disgrace to be commanded by a renegade Portuguese; and when the fleet was lying at a port in South America, which they named San Julian, a conspiracy was formed against him by three of the captains, but he discovered and quelled it. He caused the captain of one of the ships to be put to death, he boarded a second and secured the mutineers, and the third submitted.

---

[1] *Biographia Britannica*, vol. iii. art. *Cave*.

The coast on which they lay was that of Patagonia; and this first voyage contains accounts of the extraordinary stature of the natives. About the end of October they reached a cape to which they gave the name of De las Virgines, forming the entrance of the straits which now bear the name of Magellan. He exerted all his authority to induce his men to venture on this unknown passage, with the view of crossing a vast ocean beyond it, at the hazard of running short of provisions, of which a supply for three months was all that he had remaining. One of his ships abandoned him, and made the best of her way to Europe. But the rest proceeded, and on the 27th of November they discovered the South Sea, which made Magellan shed tears of joy. They continued their voyage across this ocean, now visited for the first time by Europeans, and were not long in suffering those evils from famine which they had apprehended. The men were reduced to the necessity of eating the hides with which the rigging was covered. The weather proved so uniformly calm and temperate, that they gave to the ocean the name of *Pacific.* On the 6th of March they came in sight of the Ladrones, so called from the thievish disposition of the inhabitants; and thence they sailed to the Philippines. At Zebu, Magellan obtained with little difficulty the conversion of the king; and, on condition of his becoming a vassal of Spain, the Portuguese assisted him in reducing some neighbouring chieftains, and the cross was erected over some burned villages.

With about fifty men Magellan landed upon Matan, the chief of which had refused to submit to Zebu, and an engagement took place between them, which lasted for the greater part of the day. His troops having spent all their ammunition, found it necessary to retreat, during which Magellan was wounded in the leg by an arrow, beaten down, and at last slain with a lance. This happened in 1521. By this act of imprudence he lost the honour of being the first circumnavigator of the globe, which fell to the lot of Cano, who brought his ship home by the East Indies. Yet Magellan has secured an immortal name amongst maritime discoverers, by the commencement of this great enterprise, in which he displayed extraordinary skill and resolution, but disregarded justice and humanity.

Straits of MAGELLAN, a narrow passage between the island of Tierra del Fuego and the southern extremity of the continent of America. This passage was first discovered by Ferdinand Magellan, who sailed through it into the South Sea, and thence to the East Indies. Other navigators have passed the same way; but as these straits are exceedingly difficult, and subject to storms, it has been common to sail round by Cape Horn, rather than through the Straits of Magellan.

MAGELLANIC CLOUDS, whitish appearances like clouds, seen in the heavens towards the south pole, and having the same apparent motion as the stars. They are three in number, two of them near each other. The largest lies far from the south pole; but the other two are not many degrees more remote from it than the nearest conspicuous star, that is, about eleven degrees.

MAGENTA, a city of Italy, in the delegation of Milan, in the Austrian kingdom of Venetian Lombardy, containing 3390 inhabitants.

MAGGI, JEROME, in Latin *Magius*, one of the most learned men of the sixteenth century, was born at Anghiari in Tuscany. He applied himself to all the sciences, and even to the art of war; and distinguished himself so much in this last study, that the Venetians sent him into the island of Cyprus in quality of judge of the admiralty. When the Turks besieged Famagusta, he performed all the services that could be expected from the most excellent engineer, inventing mines and machines for throwing fire, by means of which he destroyed all the works of the besiegers, and in an instant overthrew what had cost the Turks infinite labour. But the Ottomans had their revenge; for, having taken the city in 1571, they plundered his library, carried him loaded with chains to Constantinople, and treated him in the most inhuman and barbarous manner; nevertheless he comforted himself by the example of Æsop, Menippus, Epictetus, and other learned men; and, after passing the whole day in the meanest drudgery, he spent the night in writing. By the help of his memory alone, he composed treatises filled with quotations, which he dedicated to the imperial and French ambassadors. These ministers, moved by compassion for this learned man, resolved to purchase him; but whilst they were treating for his ransom, Maggi found means to make his escape, and to get to the imperial ambassador's house; when the grand visir, being enraged at his flight, and remembering the great mischief he had done to the Turks during the siege of Famagusta, sent to have him seized, and caused him to be strangled in prison in 1572. His principal works are, 1. A Treatise on the Bells of the Ancients; 2. On the Destruction of the World by Fire; 3. Commentaries on Æmilius Probus's Lives of Illustrious Men; 4. Commentaries on the Institutes. These works are written in elegant Latin. He also wrote a treatise on fortification, in Italian; and a book on the situation of ancient Tuscany. He ought not to be confounded with his brother Bartolomeo Maggi, a physician at Bologna, who wrote a treatise on gunshot wounds; nor with Vincent Maggi, a native of Bresse, and a celebrated professor of humanity at Ferrara in Padua, who was the author of several works.

MAGGIORE, LAGO, a beautiful lake, situated on the confines of Switzerland and Italy, on the south side of the Alps. It is about fifty miles long, and four or five miles broad, and is bent into a very irregular figure.

MAGGOT, the common name of the fly-worm bred in flesh, from the egg of the great blue flesh-fly.

MAGI, or MAGICIANS, an ancient religious sect in Persia, and other countries, who maintained that there were two principles, one the cause of all good, the other the cause of all evil; and, abominating the adoration of images, they worshipped God only by fire, which they looked upon as the brightest and most glorious symbol of Oromasdes or the good god, as darkness is the truest symbol of Ahriman or the evil god. This religion was reformed by Zoroaster, who maintained that there was one supreme independent Being, and under him two principles or angels, one the angel of goodness and light, and the other the angel of evil and darkness; that there is a perpetual struggle between them, which shall last to the end of the world; that then the angel of darkness and his disciples shall go into a world of their own, where they shall be punished in everlasting night; and that the angel of light and his disciples shall also go into a world of their own, where they shall be rewarded in everlasting day. The priests of the Magi were the most skilful mathematicians and philosophers of the ages in which they lived, insomuch that a learned man and a magician became equivalent terms. The vulgar looked on their knowledge as supernatural; and hence those who practised wicked and mischievous arts, taking upon themselves the name of *magicians*, drew on it that ill signification which the word now bears amongst civilised nations.

MAGIC (*Magice*, Μαγεια), in its ancient sense, the science or discipline and doctrine of the Magi, or wise men of Persia.

The origin of magic and the magi is ascribed to Zoroaster. Salmasius derives the very name from Zoroaster, who, he says, was surnamed *Mag*, whence Magus. But others, instead of making him the author of the Persian philosophy, represent him only as the restorer and improver thereof, alleging, that many of the Persian rites in use amongst the Magi were borrowed from the Zabii or Chaldæans, who agreed in many things with the Magi of the Persians; and hence some make the name *Magus* common both to the Chaldæans and Persians. Thus Plutarch mentions, that Zoroaster instituted Magi amongst the Chaldæans, in imitation of which the Persians had also theirs.

Magic, in a more modern sense, is a science which teaches to perform wonderful and surprising feats, or to produce unexpected effects.

The word *magic* originally carried with it a very innocent, nay, laudable meaning, being used purely to signify the study of wisdom, and the more sublime parts of knowledge; but as the ancient Magi engaged themselves in astrology, divination, sorcery, and the like, the term *magic* became in time odious, and was only used to signify an unlawful and diabolical kind of science, depending on the assistance of the devil and departed souls.

If any wonder how so vain and deceitful a science should ever have gained credit and authority over men's minds, Pliny solves the mystery. It is, says he, because it has possessed itself of three sciences in the most esteem amongst men, taking from each all that is great and marvellous in it. Nobody doubts but it had its origin in medicine; and that it insinuated itself into the minds of the people, under pretence of affording extraordinary remedies. To these fine promises it added every thing in religion that is pompous and splendid, and that appears calculated to blind and captivate mankind. Lastly, it mingled with the rest judicial astrology, persuading people, curious of futurity, that it saw every thing to come in the heavens. Agrippa divides magic into three kinds; natural, celestial, and ceremonial or superstitious.

Natural Magic is no more than the application of natural active causes to passive subjects, by means of which many surprising, but yet natural, effects are produced.

In this way many of our experiments in natural philosophy, especially those of electricity, optics, and magnetism, have a kind of magical appearance, and amongst the ignorant and credulous might easily pass for miracles. Such, without doubt, have been some of those miracles wrought by ancient magicians, whose knowledge of the various powers of nature, there is reason to believe, was much greater than modern vanity will sometimes allow.

Baptista Porta wrote a treatise of natural magic, or secrets for performing extraordinary things by natural causes. The natural magic of the Chaldæans was nothing but the knowledge of the powers of simples and minerals. The magic which they called *theurgia* consisted wholly in the knowledge of the ceremonies to be observed in the worship of the gods, in order to be acceptable. By virtue of these ceremonies they believed they could converse with spiritual beings, and cure diseases.

Celestial Magic borders nearly on judicial astrology. It attributes to spirits a kind of rule or dominion over the planets, and to planets a dominion over men; and on these principles builds a ridiculous kind of system.

Superstitious Magic consists in the invocation of devils. Its effects are usually evil and wicked, though very strange, and seemingly surpassing the powers of nature, being supposed to be produced by virtue of some compact, either tacit or express, with evil spirits; but the truth is, these have not all the power which is usually imagined, nor do they produce those effects which are ordinarily ascribed to them.

This species of magic, there is every reason to believe, had its origin in Egypt, the native country of paganism. The first magicians mentioned in history were Egyptians; and that people, so famed for early wisdom, believed not only in the existence of demons, the great agents in magic, but also that different orders of those spirits presided over the elements of earth, air, fire, and water, as well as over the persons and affairs of men. Hence they ascribed every disease with which they were afflicted to the immediate agency of some evil demon. When a person was seized with a fever, for instance, they did not think it necessary to search for any natural cause of the disease; it was immediately attributed to some demon which had taken possession of the body of the patient, and which could not be ejected but by charms and incantations.

These superstitious notions having spread from Egypt over all the East, the Jews imbibed them during their captivity in Babylon. Hence we find them in the writings of the New Testament attributing almost every disease to which they were incident to the immediate agency of devils. Many of the same impious superstitions were brought from Egypt and Chaldæa by Pythagoras, and transmitted by him and his followers to the Platonists in Greece. This is apparent from the writers of the life of Pythagoras. Jamblicus, speaking of the followers of that philosopher, says expressly that they cured certain diseases by incantations; and Porphyry adds, that they cured diseases both of the mind and of the body by songs and incantations. This was exactly the practice of the Egyptian priests, who were all supposed to keep up a constant intercourse with demons, and to have the power of controlling them by magical charms and sacred songs. Agreeably to this practice of his masters, we are told that Pythagoras directed that certain diseases of the mind, doubtless those which he attributed to the agency of demons, should be cured partly by *incantations*, partly by *magical hymns*, and partly by *music*.

It was the universal belief of the ancient nations, says the learned Mosheim, and especially of the orientals, that certain sounds and words, for the most part barbarous, were highly grateful, and that others were equally disagreeable, to these spirits. Hence, when they wished to render a demon propitious, and to employ him on any particular office, the magicians composed their sacred songs of the words which were believed to be agreeable to him; and when it was their intention to drive him from themselves or others, they sung in a strain which they fancied a demon could not hear but with horror. From the same persuasion arose the custom of suspending from the neck of a sick person, whose disease was supposed to be inflicted by a demon, an amulet, sometimes made of gold and sometimes of parchment, on which was written one or more of those words which demons could not bear either to hear or to see; and in a didactic poem on the healing art, still extant, we are taught by Serenus Sammonicus, that the word *Abracadabra* is an infallible remedy for a semitertian fever or ague; and to banish grief of heart, Marcellinus thinks nothing more effectual than the word *καριαγαων*. In more modern times, as we are informed by Agrippa, the words employed by those in compact with the devil, to invoke him, and to succeed in what they undertake, are, *Dies*, *mies*, *jesquet*, *benedoefet*, *douvima*, *enitemaus*. There are a hundred other formulas of words composed at pleasure, or gathered from several different languages, or patched from the Hebrew, or formed in imitation of that language. And amongst the primitive Christians there was a superstitious custom, of which we suspect some remains may yet be found amongst the illiterate vulgar in different countries, of fastening to the neck of a sick person, or to the bed upon which he lay, some text from the New Testament, and especially the first two or three verses of the Gospel of St John, as a charm undoubtedly efficacious to banish the disease.

The revival of learning, and the success with which the laws of nature have been investigated, have long ago banished this species of superstition from all the enlightened nations of Europe.

Magic Square.

Magic Square, a square figure, formed of a series of numbers in mathematical proportion, so disposed in parallel and equal ranks, that the sums of each row, taken either perpendicularly, horizontally, or diagonally, are equal.

Let the several numbers which compose any square number (for instance, 1, 2, 3, 4, 5, &c. to 25, the square number, inclusive) be disposed in their natural order after each other in a square figure of twenty-five cells, each in its cell; if now you change the order of these numbers, and dispose them in the cells in such manner that the five numbers which fill a horizontal rank of cells, being added together, shall make the same sum with the five numbers in any other rank of cells, whether horizontal or vertical, and even the same number with the five in each of the two diagonal ranks; this disposition of numbers is called a *magic square*, in opposition to the former disposition, which is called a *natural square*. See the figures following.

Natural Square.

1	2	3	4	5
6	7	8	9	10
11	12	13	14	15
16	17	18	19	20
21	22	23	24	25

15	6	4	23	17
24	18	12	10	1
7	5	21	19	13

One would imagine that these magic squares had that name given them because this property of all their ranks, which, taken any way, make always the same sum, appeared extremely surprising, especially in certain ignorant ages, when mathematics passed for magic; but there is a great deal of reason to suspect that these squares merited their name still further, by the superstitious operations they were employed in, as the construction of talismans, and the like; for, according to the childish philosophy of those days, which attributed virtues to numbers, what virtue might not be expected from numbers which appeared so wonderful?

However, what was at first the vain practice of makers of talismans and conjurers, has since become the subject of serious research amongst mathematicians; not that they imagine it will lead them to any thing of solid use or advantage (magic squares savour too much of their original to be of any great use), but only as it is a kind of play, where the difficulty makes the merit, and it may chance to produce some new views of numbers, which mathematicians will not lose the occasion of discovering.

Moschopulus, a Greek author of no great antiquity, is the first who appears to have spoken of magic squares; and, by the age in which he lived, there is reason to imagine he did not look on them merely as a mathematician. However, he has left us some rules for their construction. In the treatise of Cornelius Agrippa, so much accused of magic, we find the squares of seven numbers, viz. from three to nine inclusive, disposed magically; and it must not be supposed that these seven numbers were preferred to all the others without some very good reason. In effect, it is because their squares, according to the system of Agrippa and his followers, are planetary. The square of 3, for instance, belongs to Saturn; that of 4 to Jupiter; that of 5 to Mars; that of 6 to the Sun; that of 7 to Venus; that of 8 to Mercury; and that of 9 to the Moon. Bachet applied himself to the study of magic squares, on the hint which he had taken from the planetary squares of Agrippa, as being unacquainted with the work of Moschopulus, which is only in manuscript in the French king's library; and, without the assistance of any author, he found out a new method for those squares whose root is uneven, for instance twenty-five, forty-nine, &c. but he could not make any thing of those whose root is even.

After him came Frenicle, who took the same subject in hand. A certain great algebraist was of opinion, that whereas the sixteen numbers which compose the square might be disposed 20922789888000 different ways in a natural square (as from the rules of combination it is certain they may), they could not be disposed in a magic square above sixteen different ways; but Frenicle showed that they might be thus disposed 878 different ways; and hence it appears how much his method exceeds the former, which only yielded the fifty-fifth part of magic squares of that of Frenicle.

To this inquiry he thought fit to add a difficulty that had not yet been considered. The magic square of 7, for instance, being constructed, and its forty-nine cells filled, if the two horizontal ranks of cells, and, at the same time, the two vertical ones, the most remote from the middle, be retrenched, that is, if the whole border or circumference of the square be taken away, there will remain a square whose root will be 5, and which will only consist of twenty-five cells. Now it is not at all surprising that the square should be no longer magical, because the ranks of the large ones were not intended to make the same sum, excepting when taken entire with all the seven numbers that fill their seven cells; so that being mutilated each of two cells, and having lost two of their numbers, it may be well expected that their remainders will not any longer make the same sum. But Frenicle would not be satisfied, unless, when the circumference or border of the magic square was taken away, and even any circumferences at pleasure, or, in fine, several circumferences at once, the remaining square was still magical; which last condition, no doubt, made these squares vastly more magical than ever.

Again, he inverted that condition, and required that any circumference taken at pleasure, or even several circumferences, should be inseparable from the square; that is, that it should cease to be magical when they were removed, and yet continue magical after the removal of any of the rest. Frenicle, however, gives no general demonstration of his methods, and frequently seems to have no other guide but chance. It is true, his book was not published by himself, nor did it appear till after his death, viz. in 1693.

In 1703, Poignard, a canon of Brussels, published a treatise of sublime magic squares. Before him there had been no magic squares constructed but for series of natural numbers that formed a square; but Poignard made two very considerable improvements. Instead of taking all the numbers that fill a square, for instance, the thirty-six successive numbers, which would fill all the cells of a natural square whose side is 6, he only takes as many successive numbers as there are units in the side of the square, which, in this case, are six; and these six numbers alone he disposes in such manner in the thirty-six cells, that none of them are repeated twice in the same rank, whether it be horizontal, vertical, or diagonal; whence it follows, that all the ranks, taken all the ways possible, must always make the same sum, which Poignard calls repeated progression. Instead of being confined to take these numbers according to the series and succession of the natural numbers, that is, in an arithmetical progression, he takes them likewise in a geometrical progression, and even in an harmonical progression. But with these two last progressions the magic must necessarily be different from what it was. In the squares filled with numbers in geometrical progression, it consists in this, that the products of all the ranks are equal; and in the harmonical progression, the numbers of all the ranks continually follow that progression. He makes squares of each of these three progressions repeated.

The book of Poignard gave occasion to M. de la Hire to turn his thoughts the same way, which he did with such success that he seems to have well nigh completed the theory of magic squares. He first considers uneven squares, all his predecessors on the subject having found the construction of even ones by much the most difficult, for which reason M. de la Hire reserves these for the last. This excess of difficulty may arise partly from this, that the numbers are taken in arithmetical progression. Now in that progression, if the number of terms be uneven, that in the middle has some properties which may be of service; for instance, being multiplied by the number of terms in the progression, the product is equal to the sum of all the terms.

M. de la Hire proposes a general method for uneven squares, which has some similitude to the theory of compound motions, so useful and fertile in mechanics. As that consists in decomposing motions, and resolving them into others more simple; so does M. de la Hire's method consist in resolving the square that is to be constructed, into two simple and primitive squares. It must be owned, however, it is not quite so easy to conceive these two simple and primitive squares in the compound or perfect square, as in an oblique motion to imagine a parallel and perpendicular one.

Suppose a square of cells, whose root is uneven, for instance 7; and that its forty-nine cells are to be filled magically with numbers, for instance the first 7; M. de la Hire, on the one side, takes the first seven numbers, beginning with unity, and ending with the root 7, and on the other, 7, and all its multiples to forty-nine exclusively; and as these only make six numbers, he adds 0, which makes this an arithmetical progression of seven terms as well as the other, viz. 0, 7, 14, 21, 28, 35, 42. This done, with the first progression repeated, he fills the square of the root magically. In order to this, he writes in the first seven cells of the first horizontal rank the seven numbers proposed, in what order he pleases, for that is absolutely indifferent; and it is proper to observe here, that these seven numbers may be ranged in 5040 different manners in the same rank. The order in which they are placed in the first horizontal rank, be it what it will, is that which determines their order in all the rest. For the second horizontal rank, he places in its first cell, either the third, the fourth, the fifth, or the sixth number, from the first number of the first rank; and after that he writes the six others in order as they follow. For the third horizontal rank, he observes the same method with regard to the second that he observed in the second with regard to the first, and so of the rest. For instance, suppose the first horizontal rank filled with the seven numbers in their natural order, 1, 2, 3, 4, 5, 6, 7, the second horizontal rank may either commence with 3, with 4, with 5, or with 6; but in this instance it commences with 3; the third rank therefore must commence with 5, the fourth with 7, the fifth with 2, the sixth with 4, and the seventh with 6. The commencement of the ranks which follow the first being thus determined, the other numbers, as we have already observed, must be written down in the order in which they stand in the first, going on to 5, 6, and 7, and returning to 1, 2, &c. till every number in the first rank be found in every rank underneath, according to the order arbitrarily pitched upon at first. By this means it is evident that no number whatever can be repeated twice in the same rank; and by consequence, that the seven numbers 1, 2, 3, 4, 5, 6, 7, being in each rank, must of necessity make the same sum.

1	2	3	4	5	6	7
3	4	5	6	7	1	2
5	6	7	1	2	3	4
7	1	2	3	4	5	6
2	3	4	5	6	7	1
4	5	6	7	1	2	3
6	7	1	2	3	4	5

It appears from this example that the arrangement of the numbers in the first rank being chosen at pleasure, the other ranks may be continued in four different manners; and since the first rank may have 5040 different arrangements, there are no less than 20,160 different modes of constructing the magic square of seven numbers repeated.

1	2	3	4	5	6	7
2	3	4	5	6	7	1
3	4	5	6	7	1	2
4	5	6	7	1	2	3
5	6	7	1	2	3	4
6	7	1	2	3	4	5
7	1	2	3	4	5	6

1	2	3	4	5	6	7
7	1	2	3	4	5	6
6	7	1	2	3	4	5
5	6	7	1	2	3	4
4	5	6	7	1	2	3
3	4	5	6	7	1	2
2	3	4	5	6	7	1

The order of the numbers in the first rank being determined; if, in beginning with the second rank, the second number 2, or the last number 7, should be pitched upon in one of these cases, and repeated; and in the other case, the other diagonal would be false unless the number repeated seven times should happen to be 4; for four times seven is equal to the sum of 1, 2, 3, 4, 5, 6, 7: and in general, in every square consisting of an unequal number of terms, in arithmetical progression, one of the diagonals would be false according to these two constructions, unless the term always repeated in that diagonal were the middle term of the progression. It is not, however, at all necessary to take the terms in an arithmetical progression; for, according to this method, one may construct a magic square of any numbers at pleasure, whether they be according to any certain progression or not. If they be in an arithmetical progression, it will be proper, out of the general method, to except those two constructions which produce a continual repetition of the same term in one of the two diagonals, and only to take in the case in which that repetition would prevent the diagonal from being just; which case being absolutely disregarded when we computed that the square of 7 might have 20,160 different constructions, it is evident, that by taking that case in, it must have vastly more.

To begin the second rank with any other number besides the second and the last, must not, however, be looked on as an universal rule. It holds good for the square of 7; but if the square of 9, for instance, were to be constructed, and the fourth figure of the first horizontal rank were pitched on for the first of the second, the consequence would be, that the fifth and eighth horizontal ranks would likewise commence with the same number, which would therefore be repeated three times in the same vertical rank, and occasion other repetitions in all the rest. The general rule, therefore, must be conceived thus: Let the number in the first rank pitched on for the commencement of the second, have such an exponent for its quota; that is, let the order of its place be such that, if an unit be taken from it, the remainder will not be any just quota part of the root of the square, that is, cannot divide it equally. If, for example, in the square of 7, the third number of the first horizontal rank be pitched on for the first of the second, such construction will be just; because the exponent of the place of that number, viz. 3, subtracting 1, that is, 2, cannot divide 7. Thus also might the fourth number of the same first rank be chosen, because 4 —1, or 3, cannot divide 7; and, for the same reason, the fifth or sixth number might be taken; but in the square of 9, the fourth number of the first rank must not be taken, because 4 —1, or 3, does divide 9. The reason of this rule will appear very evident, by considering in what manner the returns of the same numbers do or do not happen, taking them always in the same manner in any given series. And hence it follows, that the fewer divisions the root of any square to be constructed has, the more numerous are the different modes of constructing it; and that the prime numbers, *i. e.* those which have no divisions, as 5, 7, 11, 13, &c. are those whose squares will admit of the most variations in proportion to their quantities.

The squares constructed according to this method have some particular properties not required in the problem; for the numbers that compose any rank parallel to one of the two diagonals, are ranged in the same order with the numbers that compose the diagonal to which they are parallel. And as any rank parallel to a diagonal must necessarily be shorter, and have fewer cells, than the diagonal itself, by adding to it the corresponding parallel, which has the number of cells by which the other falls short of the diagonal, the numbers of these two parallels, placed as it were end to end, still follow the same order with those of the diagonal; besides that their sums are likewise equal, so that they are magical on another account. Instead of the squares which we have hitherto formed by horizontal ranks, one might also form them by vertical ones; the case is the same in both.

First Primitive.

1	2	3	4	5	6	7
3	4	5	6	7	1	2
5	6	7	1	2	3	4
7	1	2	3	4	5	6
2	3	4	5	6	7	1
4	5	6	7	1	2	3
6	7	1	2	3	4	5

All that we have hitherto said regards only the first primitive square, whose numbers, in the proposed example, were 1, 2, 3, 4, 5, 6, 7; there still remains the second primitive, whose numbers are 0, 7, 14, 21, 28, 35, 42. M. de la Hire proceeds in the same manner here as in the former case; and this may likewise be constructed in 20,160 different modes, as containing the same number of terms with the first. Its construction being made, and of consequence all its ranks making the same sum, it is evident, that if we bring the two into one, by adding together the numbers of the two corresponding cells of the two squares, that is, the two numbers of the first of each, the two numbers of the second, of the third, &c. and dispose them in the forty-nine corresponding cells of a third square, it will likewise be magical in regard to its rank, formed by the addition of equal sums to equal sums, which must of necessity be equal amongst themselves. All that remains in doubt is, whether or no, by the addition of the corresponding cells of the two first squares, all the cells of the third will be filled in uch a manner that each not only contains one of the numbers of the progression from 1 to 49, but also that this number be different from any of the rest, which is the end nd design of the whole operation.

Second Primitive.

0	7	14	21	28	35	42
21	28	35	42	0	7	14
42	0	7	14	21	28	35
14	21	28	35	42	0	7
35	42	0	7	14	21	28
7	14	21	28	35	42	0
28	35	42	0	7	14	21

As to this it must be observed, that if, in the construcion of the second primitive square, care has been taken, in he commencement of the second horizontal rank, to oberve an order with regard to the first, different from what was observed in the construction of the first square; for nstance, if the second rank of the rst square began with the third erm of the first rank, and the second rank of the second square commence with the fourth of the rst rank, as in the example it actually does; each number of the rst square may be combined once, and only once, by addition with all he numbers of the second. And the numbers of the first are here 2, 3, 4, 5, 6, 7, and those of the econd, 0, 7, 14, 21, 18, 35, 42; by combining them in is manner we have all the numbers in the progression om 1 to 49, without having any of them repeated; which the perfect magic square proposed.

Perfect Square.

1	9	17	25	33	41	49
24	32	40	48	7	8	16
47	6	14	15	23	31	39
21	22	30	38	46	5	13
37	45	4	12	20	28	29
11	19	27	35	36	44	3
34	42	43	2	10	18	26

The necessity of constructing the two primitive squares a different manner does not at all prevent each of the 20,160 constructions of the one from being combined with all the 20,160 constructions of the other; of consequence, therefore, 20,160 multiplied by itself, which makes 406,425,600, is the number of different constructions that may be made of the perfect square, which here consists of the forty-nine numbers of the natural progression. But as we have already observed that a primitive square of seven numbers repeated may have above 20,160 several constructions, the number 406,425,600 must come vastly short of expressing all the possible constructions of a perfect magic square of the forty-nine first numbers.

As to the even squares, M. de la Hire constructs them, like the uneven ones, by two primitive squares; but the construction of primitives is different in general, and may be so a great number of ways; and those general differences admit of a great number of particular variations, which give as many different constructions of the same even square. It seems scarcely possible to determine exactly, either how many general differences there may be between the construction of the primitive squares of an even square and an uneven one, or how many particular variations each general difference may admit of; and, of consequence, we are still far from being able to determine the number of different constructions of all those that may be made by the primitive squares.

Dr Franklin seems to have carried this curious speculation farther than any of his predecessors in the same way. He has constructed not only a magic square of squares, but likewise a magic circle of circles. The details are not, however, of such importance as to require particular notice in this place.

MAGICIAN, one who practises magic, or has the power of performing wonderful feats by the agency of spirits.

MAGINDANAO, the most southerly of the Philippine Islands, in the Eastern Seas, and situated principally between the sixth and tenth degrees of north latitude. It is of an extremely irregular shape, and may be estimated at 300 miles in length by 105 in average breadth. This island is of a very singular shape, having three remarkable promontories, one near Samboangan to the westward, Cape St Augustine to the eastward, and Surigao to the northward. It may be divided into three parts, under distinct and independent governments; the first, under the sultan, who resides at the town of Mindanao or Selangan, formerly comprehending the greater part of the sea-coast; the second, under the Spaniards, comprehending a large portion of the sea-coast to the west, north, and north-east, where they have settled colonies of Christians from the Philippines; the third, under the sultans or rajahs, who inhabit the banks of the Great Lake, or Lano, and thence a good way inland towards the hills. This island is so remarkably indented by the sea, that it is extremely favourable to piracy, and has always been the haunt of pirates. The interior of the island is intersected by lofty chains of mountains, with intervening plains, which afford pasture for vast herds of cattle. The country is well watered and well wooded, and covered towards the sea-coast with impenetrable jungle and forests. Rice is abundantly produced, also yams, sweet potatoes, and generally all the fruits common to the tropical climates. Gold is found in the sands of the rivers, and in the mountains. The exports consist of wax, rice, cassia, rattans, tobacco, pepper, &c. All sorts of cloth are here in great demand, especially long cloth, white and blue, and red handkerchiefs of all kinds; chintz, with dark grounds; Surat goods, and all kinds of European cutlery. Many articles of Chinese manufacture have been imported. The inhabitants have not made any great advances in civilization. They can manufacture nothing beyond a common nail. They are, however, much given to cock-fighting. The women do not suffer the same confinement as in other eastern countries.

Magellan first took possession of this island in 1521, in the name of Charles V.; and the Spaniards made some settlements, and subdued the northern coast, but never made any farther progress, and now with difficulty retain their feeble colonies. It was visited by the Portuguese about the year 1537, and by the Dutch in 1607, 1616, and 1627. The intercourse of the British with this island has not been frequent. The pirates, by whom it is inhabited, made an attack on the British settlements on Prince of Wales Island in 1788, and were repulsed with loss. In 1798 the sultan seized a boat's crew of a British frigate, who were afterwards ransomed. In 1803 they fitted out a fleet of prows with a view of invading the Company's settlements in Celebes, when they were met by the Swift cruiser, and dispersed with great loss. Long. 119. 30. to 125. E. Lat. 5. 40. to 9. 55. N. The principal town of the island is of the same name, and the residence of the sultan. It is situated about six miles up the Pelangy or Magindanao River, and forms, properly speaking, one town with Selangan, which is on the opposite side of the river, communicating by several bridges. It extends about one mile down the river Pelangy, forming a tolerable street, about half the distance. Long. 124. 40. E. Lat. 7. 9. N.

MAGISTERY, an old term in chemistry, given to precipitates. Thus, *magistery* and *precipitate* are synonymous; formerly precipitate was a general term, and magistery applied to particular precipitates, such as the magistery of bismuth, and the like.

MAGISTRATE, any public officer to whom the executive power of the law is committed, either wholly or in part.

MAGLIABECHI, Antonio, a person of great learning, and remarkable for an amazing memory, was born at Florence in the year 1633. His father died when he was only seven years of age. His mother had him taught grammar and drawing, and then put him as apprentice to one of the best goldsmiths in Florence. When he was about sixteen years old, his passion for learning began to appear; and he laid out all his money in buying books. Becoming acquainted with Michel Ermini, librarian to the Cardinal de' Medici, he perfected himself by his assistance in the Latin tongue, and in a little time became master of the Hebrew. His name soon became famous amongst the learned. A prodigious memory formed his distinguishing talent; and he retained not only the sense of what he had read, but frequently all the words, and the very manner of spelling. It is said that a gentleman, to make trial of the force of his memory, lent him a manuscript he was going to print. Some time after it was returned, the gentleman, going to him with a melancholy countenance, pretended it was lost, and requested Magliabechi to recollect what he remembered of it; upon which he wrote the whole, without missing a word. He generally shut himself up the whole day, and opened his doors in the evening to the men of letters who came to converse with him. His attention was so absorbed by his studies, that he often forgot the most urgent wants of nature. Cosmo III. grand duke of Florence, made him his librarian; but he still continued negligent in his dress, and simple in his manners. An old cloak served him for a morning gown in the day, and for bed-clothes at night. The duke, however, provided for him a commodious apartment in his palace, which he was with difficulty persuaded to take possession of, but which he quitted four months afterwards, and returned to his house. He was remarkable for his extraordinary modesty, his sincerity, and his beneficence, which his friends often experienced in their wants. He was a patron of men of learning, and had the highest pleasure in assisting them with his advice and information, and in furnishing them with books and manuscripts. He had the utmost aversion to any thing that looked like constraint, and therefore the grand duke always dispensed with his personal attendance, and sent him his orders in writing. Though he lived a very sedentary life, he reached the eighty-first year of his age; and died amidst the regrets of the public, after enjoying, during the latter part of his life, such affluence as few have ever procured by their learning. By his will, he left a very fine library to the public, with a fund for its support. See the article Libraries.

MAGLIANO, a town of the province of Mondovi, in Piedmont, containing 1680 inhabitants.

MAGLOIRE, St, a native of Wales, in Great Britain, and cousin-german to St Sampson and St Mallo. He embraced a monastic life, and went into France, where he was made abbot of Dol, and afterwards provincial bishop in Bretagne. He subsequently founded a monastery in the island of Jersey, where he died on the 14th of October 575, about the age of eighty. His remains were transported to the suburb of St Jacques, and deposited in a monastery of Benedictines, which was ceded to the fathers of the Oratory in 1628. It became the seminary of St Magloire, and celebrated on account of the learned men whom it has produced. This saint cultivated poetry with considerable success, the hymn which is sung at the feast of All Saints, *Cœlo quos eadem gloria consecrat,* having been composed by him.

MAGNAC-LAVAL, a town of France, in the department of the Upper Vienne, and arrondissement of Ballac, situated on the river Brame, and containing 2850 inhabitants.

MAGNANIMITY denotes greatness of mind, particularly in circumstances of trial and adversity. It has been justly observed, that it is pride in the good sense, and the noblest way of acquiring applause. It renders the soul superior to the trouble, disorder, and emotion, which the appearance of great danger might excite; and it is by this quality that heroes maintain their tranquillity, and preserve the free use of their reason, amidst the most dreadful accidents. It admires the same quality even in an enemy; and fame, glory, conquests, desire of opportunities to pardon and oblige their opponents, are the emotions which glow in the minds of the brave.

MAGNESIA, a town of Asia Minor, situated on the Mæander, about fifteen miles from Ephesus. Themistocles died at Magnesia, which was one of the three towns given him by Artaxerxes, "to furnish his table with bread." It is also celebrated for a battle which was fought there, 190 years before the Christian era, between the Romans and Antiochus king of Syria. It was founded by a colony from Magnesia in Thessaly; and was commonly called *Magnesia ad Mæandrum,* to distinguish it from another called *Magnesia ad Sipylum,* in Lydia, at the foot of Mount Sipylus.

MAGNETICAL Island, an island in the Southern Pacific Ocean, near the north coast of New Holland, discovered by Captain Cook in 1770, and so named from its having some effect on the compass. Long. 213. 22. W. Lat. 19. 8. S.

MAGNETISM.

The word magnetism is derived from the Greek word *μαγνης*, a name given to the *loadstone* or *native magnet*, an ore of iron well known to the ancients. The term *μαγνης* itself is said to be derived from one *Magnes*, a Greek shepherd, who observed on Mount Ida the attractive power which the loadstone exercised upon his iron crook. The most probable supposition however is, that it took its name from *Magnesia*, a country in Lydia, where it was first discovered; and this conjecture is confirmed by the fact that the magnet was often called by the ancients *Lapis Heracleus*, from *Heraclea*, the capital of *Magnesia*.

The science of magnetism treats of the phenomena exhibited by magnets, whether natural like the loadstone, or artificial like bars of steel to which magnetism has been permanently communicated;—of their reciprocal action upon each other; of the laws of the forces which they develope; of the methods of making artificial magnets; and of the magnetic phenomena exhibited by the globe which we inhabit.

In giving an account of this interesting science, which has made rapid progress in modern times, we shall adopt the following arrangement:

1. On the history of magnetical discovery.
2. On the general phenomena and principles of natural and artificial magnets.
3. On the magnetism of bodies not ferruginous.
4. On the development of magnetism in bodies by rotation.
5. On the influence of heat on magnetism.
6. On the action of iron spheres on the needle.
7. On the influence of magnetism on chemical action.
8. On the laws of magnetic forces.
9. On terrestrial magnetism.
10. On the different methods of making artificial magnets.
11. On magnetical instruments and apparatus.
12. On the theories of magnetism.

CHAP. I.—ON THE HISTORY OF MAGNETICAL DISCOVERIES.

The attractive power of the natural magnet or loadstone over small pieces of iron seems to have been known from the remotest antiquity. It is distinctly referred to by Homer, Pythagoras, and Aristotle. Pliny mentions a chain of iron rings suspended from one another, the first being upheld by the loadstone; and he relates that Dinocares proposed to Ptolemy Philadelphus to build, at Alexandria, a temple, the vault of which, crowned with loadstones, should suspend in the air an iron statue of Queen Arsinöe. St Augustin likewise makes mention of a statue suspended in the air in the middle of the temple of Serapis at Alexandria. From references made to the magnet by Euripides, Claudian, and others, and from the experiment with the rings mentioned by Pliny,[1] it is not very improbable that the ancients were acquainted with the communicability of magnetism to iron bodies. The magnetical properties of the loadstone, like the electrical ones of amber, were supposed to be miraculous. Medical qualities of various kinds were ascribed to it; and even Hippocrates ranks it amongst the number of purgatives.

History.

In order to explain the properties of the loadstone, Thales, Anaxagoras, and others, supposed it to have a soul; while some conceived that it was surrounded with an emanation, capable of creating a vacuum, into which the iron precipitated itself.

Invention of the compass.

In his description of China, Duhalde has stated that the directive power, or polarity, of the magnet, was known to the Chinese in the earliest ages, and that the needle had been employed to guide travellers by land a thousand years before Christ; and it is stated by Humboldt, that, according to the *Peuthsaoyani*, a treatise on Medical Natural History, written under the Saong dynasty, 400 years before Columbus, the Chinese suspended the needle by a thread, and found it to decline to the south-east, and never to rest at the true south point.

Although the common properties of the loadstone were known to the ancients, and were no doubt studied even during the dark ages, yet, notwithstanding the claims of the Chinese and Arabians, the directive power of the loadstone, or of a needle touched or rubbed by it, seems to be the discovery of modern times. Are Frode, an Icelandic historian, who was born in the year 1068, and who must have written his *Landnamabok*, or history of the discovery of Iceland, about the end of the eleventh century, mentions, in the most unequivocal manner, the directive power of the loadstone as known in his day. He states that Floke Vilgerderson, a renowned viking or pirate, departed from Rogoland in Norway, to seek Gadersholm or Iceland, some time in the year 868. He carried with him three ravens as guides, and, to consecrate them for this purpose, he offered up a sacrifice in Smörsund, where his ship lay. "*For*," says Frode, "*in those times seamen had no loadstone*[2] *in the northern countries*."

A. D. 868.

That the mariner's compass was known in the twelfth century, about the year 1150, is proved by notices of it in various authors, particularly in an old French poem called *La Bible Guyot*, which is contained in a curious quarto manuscript of the thirteenth century, still existing in the Royal Library at Paris. Guyot of Provins, the author of this poem, was alive in 1181. After referring to the ways by which navigators are guided in their course, and mentioning the pole star, he adds,

Un art font qui mentir ne peut,
Par la vertue de la marinière,
Un pierre laide et brunière
Où le fers volontiers se joint,
Ont regardent lor droit point.

That is, "they possess a never-failing method, by the virtue of the marinière, an ugly and brown stone, to which iron adheres of its own accord." The author next adds, that this art consists in rubbing a needle on the *marinière;* and that the point of this needle turns just against the pole-star in dark nights, when neither star nor moon are seen.

Quant il nuit est ténèbre et brune,
Quand ne voit estoile ne lune,
Lor font à l'aiguille allumer,
Puiz ne peut ils assorer,
Contre l'estoile va le pointe,
Par se sont il mariner cointe,
De la droit voie tems:
C'est un art qui ne peut mentir.

---

[1] Sola hæc materia (ferrum) vires ab eo lapide accipit, retinetque longo tempore, aliud apprehendens ferrum, ut annulorum catena spectetur interdum, quod imperitum vulgus ferrum appellat vivum.

[2] *Leidarstein*, or *Leading Stone*, from which our word *Loadstone* is derived.

History.

A. D. 1200.

Cardinal James de Vitri, who flourished about the year 1200, mentions the magnetic needle in his History of Jerusalem; and he adds, that it was of indispensable utility to those who travelled by sea.

That the mariner's compass was known to the northern nations in 1266, appears from Torfæus's History of Norway, where it is mentioned that Jarl Sturla's poem on the death of the Swedish count Byrgeres was rewarded with a mariner's compass. The directive property of the magnet is also distinctly mentioned in an epistle of Petrus Peregrinus de Marcourt, written about the latter end of the thirteenth century. This letter was addressed "Ad Sigerium de Foueancourt militem de magnete." This epistle contains a description of the loadstone, the means of finding its poles, and its property of attracting iron; and it proves that *the part of the magnet which is turned to the north attracts that which is turned to the south.*

Paulus Venetus. A. D. 1260.

Peter Adsiger.

A Neapolitan named Flavio Gioia, who lived in the thirteenth century, has been regarded by many as the inventor of the compass. Dr Gilbert affirms that Paulus Venetus brought the compass from China to Italy in 1260. Ludi Vestomannus asserts, that about 1500 he saw a pilot in the East Indies direct his course by a magnetic needle like those now in use. One of the earliest treatises on magnetism is a Latin letter of Peter Adsiger, contained in a volume of manuscripts in the library of the university of Leyden. This letter, which appears to have been written for the instruction of a friend, is in reality a methodical treatise, in two parts, the first of which is subdivided into ten, and the second into three chapters. In the second chapter of the second part, the mariner's compass, and the method of constructing it, are clearly described; and, what is still more interesting, the author not only mentions the declination of the magnetic needle, but had observed its actual deviation from the meridian. "Take notice," says he, "that the magnet, as well as the needle which has been touched by it, does not point exactly to the poles; but that part of it which is reckoned to point to the south inclines a little to the west, and that part which looks towards the north inclines as much to the east. The exact quantity of this declination I have found, after numerous experiments, to be *five degrees.* However, this declination is no obstacle to our guidance, because we make the needle itself decline from the true south by nearly one point and a half towards the west. A point, then, contains five degrees." Mr Christie seems to consider the authenticity of this manuscript as doubtful, because no new observation of the declination seems to have been made for two centuries afterwards; and because the declination should be westerly in place of easterly in 1269, according to the best law of the change which can be deduced from subsequent observations.

Columbus. A. D. 1492.

Variation discovered.

The declination or the variation of the needle, thus distinctly described by Adsiger, if his manuscript is authentic, must be considered as well known before the time of Columbus, to whom the discovery of it has been generally ascribed. His son Ferdinand states, that on the 14th of September (13th according to Mr Irving) 1492, his father, when about two hundred leagues from the island of Ferro, noticed for the first time the variation of the needle; "a phenomenon," says Washington Irving, "which had never before been remarked." "He perceived," adds this author, "about nightfall, that the needle, instead of pointing to the north star, varied but half a point, or between five and six degrees to the north-west, and still more on the following morning. Struck with this circumstance, he observed it attentively for three days, and found that the variation increased as he advanced. He at first made no mention of this phenomenon, knowing how ready his people were to take alarm; but it soon attracted the attention of the pilots, and filled them with consternation. It seemed as if the laws of nature were changing as they advanced, and that they were entering another world, subject to unknown influences. They apprehended that the compass was about to lose its mysterious virtues; and, without this guide, what was to become of them in a vast and trackless ocean? Columbus tasked his science and ingenuity for reasons with which to allay their terrors. He told them that the direction of the needle was not to the polar star, but to some fixed and invisible point. The variation was not caused by any failing in the compass, which, like the other heavenly bodies, had its changes and revolutions, and every day described a circle round the pole. The high opinion that the pilots entertained of Columbus as a profound astronomer gave weight to his theory, and their alarm subsided."[1] Although the details which we have already given afford sufficient proof that the variation of the needle had been discovered two hundred years before the time of Columbus, yet it is evident, from the above passage, that he had discovered the variation of the variation, or that the variation was not a constant quantity, but varied in different latitudes.

Change in the variation.

Notwithstanding these casual observations on the variation of the compass, no accurate measures of its amount were made till about the middle of the 16th century. In 1541 it was found that the declination of the needle from the meridian of Paris was about 7° or 8° easterly. In 1550 it was 8° or 9°, and in 1580 $11\frac{1}{2}$° easterly. Norman,[2] who first observed the variation in London, made it 11° 15′ easterly; and Mr Burough,[3] comptroller of the navy, in 1580 found it to be at an average 11° 19′ E. at Limehouse. The following observations made at other places will show the gradual change in the variation.

Burough	1580	11°	19′	E. Limehouse.
Gunter	1612	5	36	E. London.
Gellibrand[4]	1633	4	4	E. London.
Petit	1630	4	30	E. Paris.
Petit	1660	0	10	E. Paris.
Auzout	1670	2	0	W. Rome.
Hevelius	1642	3	5	W. Dantzig.
Hevelius	1670	7	20	W. Dantzig.

Dip of the needle discovered. A. D. 1576.

The important discovery of the *dip* or inclination of the needle was made in 1576, by Robert Norman, whom we have already mentioned. Having constructed many compasses, and having always balanced the needles for them before he touched them with the magnet, he invariably found, that after they were touched, the north point always inclined below the horizon, so that he was obliged to make the card of the compass level, by putting some small pieces of wire on the end of it. Having mentioned this discovery to some of his friends, he was advised to construct an instrument which would enable him to measure the greatest angle which it would make with the horizon. With this instrument, which is the dipping needle in its first and rudest form, he found the dip to be at 71° 50′; an observation which, according to Bond, must have been made about 1576.

That ferruginous substances always possess a greater or tory History.

[4] Discourse Mathematical on the Variation of the Magnetical Needle, 1635. Gellibrand found that the north-east of the needle was gradually moving to the westward.

a less degree of magnetism, has been long known. One Julius Cæsar, a surgeon of Rimini, first observed the conversion of iron into a magnet. In 1590 he noticed this effect on a bar of iron which had supported a piece of brickwork on the top of a tower of the church of St Augustin. The very same fact was observed about 1630, by Gassendi, on the cross of the church of St John at Aix, which had fallen down in consequence of having been struck with lightning. He found the foot of it wasted with rust, and possessing all the properties of a loadstone.

lbert 1600

While magnetism was making slow advances by means of insulated observations, it was destined to receive a vigorous impulse from the pen of Dr Gilbert of Colchester. This eminent individual, who was physician in ordinary to Queen Elizabeth, published, in 1600, his *Physiologia Nova, seu Tractatus de Magnete et Corporibus Magneticis*, a work which contains almost all the information concernng magnetism which was known during the two followng centuries. It relates chiefly to the natural loadstone, and to artificial magnets, or bars of steel which have acquired similar properties. He applies the term magnetic to all bodies which are acted upon by loadstones and magnets, in the same manner as they act upon each other, and he finds that all such bodies contain iron in some state or ther. He considers the phenomena of electricity as havng a considerable resemblancc to those of magnetism, hough he points out the differences by which the two classes f phenomena are marked. In treating of the directive power of the needle, he supposed, "that the earth itself being in all its parts magnetical, and the water not, wherver the land was, there would the needle turn, as to the reater quantity of magnetical matter." He regarded the earth as acting upon a magnetised bar, and upon iron, like a magnet, the directive power of the needle being produced by the action of magnetism of a contrary kind to hat which exists at the extremity of the needle directed owards the pole of the globe. He gave the name of *pole* o the extremities of the needle which pointed towards the poles of the earth, conformably to his views of terrestrial magnetism, calling the extremity that pointed towards the *north* the *south pole* of the needle, and that which pointed o the *south* the *north pole*.

650.

About the year 1650, Mr Bond, a teacher of mathematics in London, who had been employed to superintend the publication of the popular treatises on navigation, published work called the *Seaman's Calendar*, in which he maintains that he has discovered the true progress of the deviation of the compass; and in another book, called *The Longitude Found*, and in the *Phil. Trans.* 1668, he published a table of the computed variations for London for many years to come, extending from 1663 to 1716. The results which his table contains agree very nearly with those which were observed for the next twenty-five years, but after that the differences became very great. In a subsequent paper in the *Phil. Trans.* for 1673, Bond attempted to account for he change in the variation and dip of the needle, by supposing *that the two magnetic poles revolved round the poles f the earth.* He asserted that he knew the period of his revolution, as well as its cause; and he proposed to determine the longitude by means of the dip of the needle. He did not, however, think proper to communicate either is views or method to the public.

n,

Newton, Huygens, Hooke, and some of the other philosophers who flourished about the end of the seventcenth century, were occupied, though not to a great degree, with he subject of magnetism. Some of their observations and discoveries are referred to in a manuscript volume of notes nd commentaries, written by David Gregory in 1693, in a copy of Newton's *Principia*, and used by Newton in improvng the second edition. Newton had supposed that the law f magnetic action approaches to the inverse triplicate ratio of the distance; but Gregory did not adopt this opinion, and invalidates the arguments which were used in its support. Newton committed another mistake in asserting, as we shall afterwards see, that red hot iron has no magnetic property.

Dr Hooke. A. D. 1684.

Several interesting experiments had been made by Dr Gilbert, on the effects of heat in destroying magnetism, and also in inducing it in substances susceptible of being impregnated. He likewise made numerous experiments with bars of iron and steel placed in the magnetic meridian and exposed to great heats. Dr Hooke took up this subject in 1684. He used rods of iron and steel about seven inches long and one fifth of an inch in diameter, and he found that they acquired permanent magnetism when strongly heated in the magnetic meridian, and allowed to cool in the same position. The permanency of the effect was greater, and the magnetism stronger, when the rods were suddenly cooled in cold water, so as to give them a very hard temper. He found that the end which was next to the north, or the lower end of a vertical bar, was invariably a permanent north pole. Even when the upper end alone was quenched, while the rest of the bar cooled slowly, that end became a sensible south pole. If the same process was adopted when the steel bar lay at right angles to the magnetic meridian, no magnetism was acquired.

Dr Halley. A. D. 1683.

The subject of terrestrial magnetism now occupied the attention of our eminent countryman Dr Edmund Halley; and in 1683 he published his *Theory of Magnetism*, which to a certain extent forms the nucleus of more modern hypotheses. He regarded the earth's magnetism as caused by four poles of attraction, two of them near each pole of the earth; and he supposes "that in those parts of the world which lie nearly adjacent to any one of these magnetic poles, the needle is governed thereby, the nearest pole being always predominant over that more remote." He supposes that the magnetic pole, which was in his time nearest Britain, was situated near the meridian of the land's end, and not above 7° from the north pole; the other north magnetic pole being in the meridian of California, and about 15° from the north pole of the earth. He placed one of the two south poles about 16° from the south pole of the globe, and 95° west from London; and the other, or the most powerful of the four, about 20° from the south pole, and 120° east of London.

Dr Halley's theory.

In order to account for the change in the variation, Dr Halley, some years afterwards, added to these reasonable suppositions the very extraordinary one, that our globe was a hollow shell, and that within it a solid globe revolved, in nearly the same time as the outer one, and about the same centre of gravity, and with a fluid medium between them. To this inner globe he assigned two magnetic poles, and to the outer one other two; and he conceived the change in the variation of the needle to be caused by a want of coincidence in the times of rotation of the inner globe and the external shell. "Now, supposing," says he, "such an external sphere having such a motion, we may solve the two great difficulties in every former hypothesis; for if this exterior shell of earth be a magnet, having its poles at a distance from the poles of diurnal rotation, and if the internal nucleus be likewise a magnet, having its poles in two other places, distant also from its axis, and these latter, by a gradual and slow motion, change their places in respect of the external, we may then give a reasonable account of the four magnetic poles, as also of the changes of the needle's variation." From some reasons which Dr Halley then states, he concludes "that the two poles of the external globe are fixed in the earth, and that if the needle were wholly governed by them, the variation would be always the same, with some little irregularities; but the internal sphere, having such a gradual translation of its poles, influences the needle, and directs it variously, according to the result of the attractive and directive power of each pole, and consequently there must be a period of revolution of this internal ball, after which the variation will return as before."

This theory excited so much notice, that an application was made to William and Mary, for a ship, "in order to seek, by observation, the discovery of the rule for the variation of the compass." The command of a ship of the royal navy was in consequence given to Dr Halley; and, in the accomplishment of the object which he had in view, he performed two voyages, one in 1698 and the other in 1699, in which he traversed various parts of the Pacific and Atlantic Oceans, and obtained such a number of valuable results, that he completed a chart of the variation of the needle, which exhibited to the eye the general law of its phenomena.

Graham. A. D. 1722.

Daily variation discovered.

The very important discovery of the daily variation of the needle was made in 1722, by Mr Graham, a celebrated mathematical instrument maker in London. While the needle was advancing by an annual motion to the westward, Mr Graham found that its north extremity moved westward during the early part of the day, and returned again in the evening to the eastward, to the same position which it occupied in the morning, remaining nearly stationary during the night. Mr Graham at first ascribed these changes to defects in the form of his needles; but, by numerous and careful observations, repeated under every variation of the weather and of the heat and pressure of the atmosphere, he concluded that the daily variation was a regular phenomenon, of which he could not find the cause. It was generally a maximum between ten o'clock A. M. and 4 o'clock P. M., and a minimum between six and seven o'clock P. M. Between the 6th February and the 12th May 1722, he made a thousand observations in the same place, from which he found that the greatest westerly variation was 14° 45′, and the least 13° 50′; but in general it varied between 14° 35′ and 14°, giving 35′ for the amount of the daily variation.

Law of the magnetic force.

The law of the magnetic force, or the rate at which it varies with the distance, had, as we have seen, occupied the attention of Sir Isaac Newton and David Gregory. Numerous experiments were made by various authors for the same purpose, a large collection of which have been published by Scarella, in his treatise *De Magnete*, published at Brescia in 1759. Muschenbroeck made a great number of experiments with the same view; but as the joint action of the four poles was never considered, the precise law of variation remained unknown.

Hauksbee and Brooke Taylor.

Mr Hauksbee and Dr Brooke Taylor employed a much better method, namely, the deviation of a compass-needle from the meridian, produced by the action of a magnet at different distances; but the magnets which they used had improper shapes, and the conclusion which they drew from their experiments was, that the magnetic force decreased much quicker at great distances than at small ones, and that it is different in different loadstones.[1]

Mr Michell.

Notwithstanding this strange conclusion, the observations to which we have referred were of great value; and Mr Michell[2] succeeded in deducing from them, in 1750, the true law of magnetic action. "There have been," says Mr Michell, "some who have imagined that the decrease of the magnetic attraction and repulsion is inversely as the cubes of the distances; others, as the squares; and others, that it follows no certain ratio at all, but that it is much quicker at great distances than at small ones, and that it is different in different stones. Among the last is Dr Brooke Taylor and Muschenbroeck, who seem to have been pretty accurate in their experiments. The conclusions of these gentlemen were drawn from their experiments, without their being aware of the third property of magnets just mentioned, which, if they had made proper allowances for, together with the increase and diminution of power in the magnets they tried their experiments with, all the irregularities they complained of (as far as appears from their relations of them) might very well be accounted for, *and the whole of their experiments coincide* with the squares of the distances inversely."

Torsion balance.

It is to Mr Michell also that we owe the introduction of the torsion balance, for measuring small forces; an instrument which, as we shall see, was employed with singular success and dexterity by Coulomb in his electrical, magnetical, and hydrodynamical researches: and the science of magnetism is no less indebted to Mr Michell for his invention of the method of double touch, as it is called, by which artificial magnets may be made with greater strength than could have been obtained from the previous method of Duhamel.

Descartes.

The hypothesis of Descartes, who explained the polarity of the needle by means of currents moving rapidly from the equator to the poles, was adopted and defended by Euler and Daniel Bernoulli; but we cannot afford any space for such useless speculations. Euler afterwards occupied himself more advantageously for science in attempting to investigate mathematically the direction of the needle on every part of the earth's surface.[3] Perceiving the intricacy which would arise from the adoption of four poles, as imagined by Halley, he tried the effect of employing two poles not diametrically opposite; and he found, that when a proper position was given them, the variation under the same meridian might be both easterly and westerly, as in Halley's chart. The solution which he has given is founded on the principle, "that the magnetic direction on the earth follows always the small circle which passes through the given place, and the two magnetic poles of the earth;" or that the horizontal needle is a tangent to the circle passing through the place of observation, and through the two points on the earth's surface where the dipping needle becomes vertical, or the horizontal needle loses its directive power. In the application of this principle, Euler makes four different suppositions respecting the magnetic poles: 1. That they are diametrically opposite to each other; 2. that they are in opposite meridians, but not in opposite parallels; 3. that they are on the same meridian; and, 4. that they have every other situation whatever. The first of these suppositions he finds to be quite irreconcileable with the observed phenomena, but in the other three he finds that the variation may be both easterly and westerly in the same meridian. By successive approximations he finds the position of the two magnetic poles in 1757 to be as follows: The north pole in latitude 76° north, and longitude 96° west from Teneriffe; and the south pole in latitude 58° south, and longitude 158° west from Teneriffe. To this dissertation Euler has added a chart of the curves of equal variation, calculated on the preceding principles, and suited to 1757; and their general accordance with observation is very surprising. In a subsequent dissertation Euler endeavoured to improve his theory, by supposing the two magnetic poles to be at the surface of the earth. The chord joining these poles he calls the magnetic axis, and the middle point of that chord its magnetic centre. Then, if we draw a line from the place of observation to the magnetic centre, and consider this as the base of an isosceles triangle, one of whose sides is the magnetic axis, the other side will be the direction of a freely suspended needle. This hypothesis, though it has various defects, fulfils, as has been well remarked, certain conditions that are essential to a good theory. 1. It gives the needle the approximately accurate positions at the equator, the needle and the axis being then parallel; 2. it fulfils the condition of the needle and axis, forming a continuous line at the poles; 3. it furnishes two points at which the needle would be vertical; and, 4. it gives a series of positions, single for each place, and having a certain, and oftentimes pretty close, approach to the true position.[1]

ert.
175

The law of magnetic action occupied the particular attention of M. Lambert, the celebrated Prussian philosopher, who has published an account of his labours in the Memoirs of the Academy of Berlin for 1756. Having placed a mariner's compass at various distances from a magnet, and in the direction of its axis, he observed the declination of the needle produced by the magnet, and the obliquity of the magnet to the needle's axis. From several observations at different obliquities, he found that the action of magnetism on a lever was proportional to the sine of the angle of its obliquity to the axis of the lever or needle. M. Lambert then proceeded to study the effect of distance, and he discovered that the force of a magnet is proportional to the distance of the nearest pole of the magnet from the centre of the needle, diminished by the square of a constant quantity, nearly equal to two thirds of the length of the needle. This result he found to be true with magnets ten times larger, and needles twice as short; but as the law led him to a strange result, as if the action on a magnet were exerted from a centre beyond itself, he was therefore obliged to take another method of determining the law of action, namely, by a series of experiments on the directive power of the magnet,[2] from which he inferred, "that the force of each transverse element of a magnet is as its distance from the centre, and its action as a particle of another magnet inversely as the square of the distance." By means of this law he calculates the position of a very small needle, and draws three of the curves to which it should be a tangent, and these coincide very accurately with some of those which he had observed.

bi-
769.

Our learned countryman Dr Robison had been pursuing similar inquiries before he had seen Lambert's experiments. He got some magnets made, composed of two balls connected by a slender rod; and after magnetising them strongly, he found that the force of each pole resided nearly in the centre of the ball. In this way the attractive and the directive powers of the magnets were easily computed, and the result was, that the force of each pole was inversely as the square of the distance. In no case did the error of this hypothesis amount to one fifteenth of the whole, and in the calculation for the phenomena of the directive power the errors were still smaller. When Dr Robison had seen Lambert's second memoir, he repeated all his former experiments in Lambert's manner, taking the precaution of keeping the needle in its natural position, which he had not previously attended to; and the results which he now obtained were still more conformable to his conjecture as to the law of variation. Dr Robison tried another method of ascertaining the law of magnetic action. In 1769 or 1770 he constructed a needle of two balls joined by a slender rod, and having touched it with great care, so as to keep the whole strength of the poles near the centre of the balls, he counted the number of oscillations which it performed horizontally in a given time by the force of the earth's magnetism. "He then placed it on the middle of a very fine and large magnet, placed with its poles in the magnetic meridian, the north pole pointing south. In this situation he counted the vibrations made in a given time. He then raised it up above the centre of a large magnet, till the distance of its poles from those of the great magnet was changed in a certain proportion. In this situation its vibrations were again counted. It was tried in the same way in a third situation, considerably more remote from the great magnet. Then having made the proper reduction of the forces corresponding to the obliquity of their action, the force of the poles of the great magnet was computed from the number of vibrations." The results of these experiments were the most consistent with each other of any that Dr Robison made for determining the law of the magnetic force, and it was chiefly from them that he thought himself authorized to say with some confidence, that it is inversely as the square of the distance. When Dr Robison, however, observed, some years afterwards, that Æpinus, in 1777, conceived the force to vary inversely as the simple distance, he repeated the experiments with great care, and added another set made with the same magnet, and the same needle placed at one side of the magnet instead of above it. By this arrangement, which greatly simplified the process, the result of the whole was still more satisfactory. The inverse law of the square of the distance was therefore well established.

Theory of Æpinus.
A. D. 1759.

Various speculations respecting the cause of the phenomena of magnetism had been hazarded by different authors; but it was reserved for M. Æpinus to devise a rational hypothesis, which embraced and explained almost all the phenomena which had been observed by previous authors. This hypothesis, which he has explained at great length in his *Tentamen Theoriæ Electricitatis et Magnetismi*, published in 1759, may be stated in the following manner.

1. In all magnetic bodies there exists a substance which may be called the magnetic fluid, whose particles repel each other with a force inversely as the distance.

2. The particles of this fluid attract the particles of iron, and are attracted by them in return with a similar force.

3. The particles of iron repel each other according to the same law.

4. The magnetic fluid moves through the pores of iron and soft steel with very little obstruction; but its motion is more and more obstructed as the steel increases in hardness or temper, and it moves with the greatest difficulty in hard-tempered steel and the ores of iron.

Methods of making artificial magnets.

The method of making artificial magnets, which was practised by the philosophers of the seventeenth century, was a very simple but a very inefficacious one. It consisted in merely rubbing the steel bar to be magnetised, upon one of the poles of a natural or artificial magnet, in a direction at right angles to the line joining the poles of the magnet. Towards the middle of the eighteenth century, however, the art of making artificial magnets had excited general attention; and it is to Dr Gowin Knight, an English physician, that we are indebted for the discovery of a method of making powerful magnets. This method he kept secret from the public, but it was afterwards published by Dr Wilson. Duhamel, Canton, Michell, Antheaume, Savery, Æpinus, Robison, Coulomb, Biot, Scoresby, and others, made various improvements on this art, as will be minutely described when we arrive at that part of our subject.

Experiments of Canton.
A. D. 1756.

The science of magnetism owes many obligations to Mr John Canton, one of the most active experimental philosophers who adorned the middle of the eighteenth century. In or previous to the year 1756, he made no fewer than 4000 observations on the diurnal variation of the needle, with the view of determining its amount, and investigating its origin. He found the daily change different in different seasons of the year, as shown in the following table.

---

[1] See an excellent paper on Terrestrial Magnetism, in the *Magazine of Popular Science*, May 1836, No. iv. p. 223, 224.

[2] *Memoirs of the Berlin Academy*, vol. xxii.

June	13 21	December	6 58

He found also that the time of minimum westerly variation at London was between eight and nine o'clock A. M., and the time of maximum between one and two o'clock P. M., the needle returning to its morning position about eight or nine in the evening. A series of similar observations were made with nearly the same results by Mr Van Swinden; but this excellent observer discovered, that some time before the hour in the morning when the westerly minimum took place, and after the same hour in the evening, a motion of the needle both to the eastward and westward took place; that is, the morning westerly variation is sometimes preceded by a small easterly variation, and the principal easterly variation in the evening is followed by a small westerly variation.

Van Swinden.

Canton explained the westerly variation of the needle, and the subsequent easterly motion, by supposing that the heat of the sun, acting upon the eastern parts of the earth, weakens their influence, as heat is known to do that of a magnet, and consequently the needle will move to the westward. In the same way, as the sun warms the western side of the earth in the afternoon, the needle will then take a contrary direction.

Discoveries of Coulomb.

One of the ablest cultivators of the science of magnetism was the celebrated Coulomb, who, by the application of the principle of torsion, first used by Michell, determined the correct law of magnetic attractions and repulsions.[1] After measuring with great nicety, by the torsion balance, the force requisite to make a magnetic bar suspended horizontally deviate any number of degrees from a given position, he was enabled to verify the discovery of Lambert already mentioned, that the effect of terrestrial magnetism is proportional to the sine of the angle which the magnetic meridian forms with the axis of the magnet upon which it acts. By making the homologous poles of two magnetised wires repel each other, he observed the force of torsion which was necessary to overcome certain quantities of their mutual repulsion, and, at the distances 12°, 17°, and 24°, he found that the repulsive forces were as the numbers 3312, 1692, and 864, deviating little from 3312, 1650, and 828, which they would have been had the repulsive force varied in the inverse ratio of the square of the distance. The excess of 42 and 36 in the experimental numbers was owing to the circumstance that it was not a particle, but a portion, of each wire, from which the repulsive force emanated, so that the force of the other particles being exerted less obliquely, and therefore being stronger at greater distances, ought to produce an excess such as that actually observed. A similar result was obtained when the contrary poles of the magnetised wires were made to attract each other; so that Coulomb concluded that the attractive and repulsive forces exercised by two magnetic particles are inversely as the square of their distances, a result which he confirmed by several other methods than that which we have noticed.

Distribution of magnetism.

Provided with such a delicate instrument as the torsion balance, Coulomb was enabled to apply it with singular advantage to almost every branch of the science. His first object was to determine the law according to which magnetism is distributed in a magnetic bar. It was of course well known that the magnetism in the middle of the bar was imperceptible, and that it increased according to a regular law, and with great rapidity, towards each of its poles. By suspending a small proof needle with a silk fibre, and causing it to oscillate horizontally, opposite different points of a magnetic bar placed vertically, Coulomb computed the part of the effect which was due to terrestrial magnetism, and the part which was due to the action of the bar; and in this way he obtained the following results, which show the extreme rapidity with which magnetism is increased towards the poles.

Discoveries of Coulomb.

Distances from the north end of the Bar.	Intensity of the Magnetism at these distances.
0 inches	165
1	90
2	48
3	23
4·5	9
6	6

In examining the distribution of electricity in a circular plane, Coulomb found that the thickness of the electric stratum was almost constant from the centre to within a very small distance of the circumference, when it increased all on a sudden with great rapidity. He conceived that a similar distribution of magnetism took place in the transverse section of a magnetic bar; and, by a series of nice experiments with the torsion balance, he found this to be the case, and established the important fact, that the magnetic power resides on the surface of iron bodies, and is entirely independent of their mass.

Effects of temperature.

The effect of temperature on magnets was another subject to which Coulomb directed his powerful mind; but he did not live to give an account of his experiments, which were published after his death by his friend M. Biot. Coulomb found that the magnetism of a bar magnetised to saturation diminished greatly by raising its temperature from 12° of Reaumur to 680°; and that when a magnetic bar was tempered at 780°, 860°, and 950°, of Reaumur, the development of its magnetism was gradually increased, being more than double at 900° of what it was at 780°. He found also that the directive force of the bar reached its maximum when it was tempered at a bright cherry-red heat at 900°; and that at higher temperatures the force diminished. It is to Mr Barlow, however, as we shall presently see, that we are indebted for the complete investigation of the influence of temperature on the development of magnetism.

Method of making artificial magnets.

Coulomb made many valuable experiments on the best methods of making artificial magnets, and he subjected all the various processes that had been previously employed to the test of accurate measurement. His experiments on the best forms of magnetic needles are equally valuable; but the most interesting of his researches, and the last to which he devoted his great talents, were those which relate to the action of magnets upon all natural bodies. Hitherto, iron, steel, nickel, and cobalt, had been regarded as the only magnetic bodies; but, in the year 1802, Coulomb announced to the Institute of France, that all bodies whatever are subject to the magnetic influence, even to such a degree as to be capable of accurate measurement. The substances employed by Coulomb were in the form of a cylinder or small bar, about one third of an inch in length and one thirtieth in thickness, and they were suspended by a single fibre of silk between the opposite poles of two powerful steel magnets, placed in the same straight line, and having their opposite poles at a distance exceeding by a quarter of an inch the length of the cylinders. The cylinders were then made to oscillate between the poles of the magnets, and were

Universal magnetism.

---

[1] See our article ELECTRICITY, p. 586, where the torsion balance is minutely described.

ory.

protected from all motions of the air by a glass receiver. The result of these experiments was, that whatever was the substance of the cylinders, they always arranged themselves in a line joining the poles of the magnets, and returned to that position whenever they were deflected from it. These experiments were made with cylinders of gold, silver, copper, lead, tin, glass, wood, chalk, bone, and every variety of substance, organic and inorganic. The only explanation which Coulomb could give of these phenomena was, either that all bodies whatever were susceptible of magnetism, or that they contained small portions of iron or other magnetic metals, which communicated to them the property of obeying the magnet. In order to investigate this subject, MM. Sage and Guyton prepared highly purified needles of the different metals, and M. Coulomb found that the momenta of the forces with which they were solicited by the magnets were as follows:—

Lead	0·00674
Tin	0·00591
Silver	0·00520
Gold	0·00406
Copper	0·00406

he momentum of torsion alone, for all the needles, being 0·00136, a little more than a fourth of the action which he magnets exert upon the needles.

In order to determine if these phenomena were owing o particles of iron disseminated through the bodies, Couomb fabricated needles out of three different mixtures of white wax and iron filings, and he found that the forces exerted by magnets upon these needles were proporional to the absolute quantities of iron which they conain. Coulomb now tried a needle of silver, purified by cupellation, and another needle of silver alloyed with $\frac{1}{20}$th part of iron, and he found that the action of the magnet upon the former was 415 times less than upon he latter. Hence there will be 415 times less iron in he pure than in the impure silver; and since the latter ontains $\frac{1}{320}$th part of its weight of iron, the first will ontain $\frac{1}{415}$th of $\frac{1}{320}$th, or $\frac{1}{132800}$th, or it will contain 32799 parts of pure silver and one of iron, a quantity of lloy beyond the reach of chemical detection.

boldt.

Amongst the scientific travellers who contributed to our nowledge of terrestrial magnetism, Baron Alexander Humboldt was one of the most distinguished. Himself n accurate and scientific observer, and possessed of nice nstruments and methods of observation, he made numeous accurate observations on the dip and variation of the eedle in various parts of the earth, and particularly near he magnetic equator; and, by means of these valuable ata, M. Biot was enabled to throw much light on the ubject of terrestrial magnetism. Hitherto the magnetic oles had been considered as either on or very near the urface of the earth; but as it had been found impossible o deduce the phenomena of the variation and dip of the eedle, philosophers were led to consider the situation of hese poles as indeterminate. M. Biot was the first to dopt this view of the subject; and after numerous comarisons, he came to the conclusion, that the nearer these oles were placed to each other, the greater was the greement between the computed and observed results; nd by considering the two poles as indefinitely near each ther in the centre of the earth, the computed and oberved measures approximated as closely as could be exected. Hence it was inferred that the phenomena of errestrial magnetism were not such as are produced by ermanently magnetic bodies, but those rather that arise rom simple iron or ferruginous masses, which are only temporarily magnetic. In this manner M. Biot was led to express the law of terrestrial magnetism in a complicated formula, which represented the observations with wonderful accuracy.

History.

Professor Krafft.

In the year 1809, Professor Krafft of St Petersburg undertook the very same inquiry, and after comparing the same observations which were used by Biot, with the respective situations of the places where they were obtained, he arrived at the following simple law: "If we suppose a circle circumscribed about the earth, having the two extremities of the magnetic axis for its poles, and if we consider this circle as a magnetic equator, the tangent of the dip of the needle, in any magnetic latitude, will be equal to double the tangent of this latitude." Upon re-examining his former formula, M. Biot found that it was reducible to the above simple law, a coincidence which may be considered as giving it additional confirmation.

Professor Hansteen.

One of the most zealous and successful cultivators of magnetical science is Professor Hansteen of Christiania, who published, in 1817, an able work on the magnetism of the earth.[1] The Royal Society of Denmark proposed, in 1811, the prize question, "Is the supposition of one magnetical axis sufficient to account for the magnetical phenomena of the earth, or are two necessary?" Professor Hansteen's attention had been previously drawn to this subject by seeing a terrestrial globe, on which was drawn an elliptical line round the south pole, and marked *Regio Polaris magnetica*, one of the foci being called *Regio fortior*, and the other *Regio debilior*. As this figure professed to be drawn by Wilcke, from the observations of Cook and Furneaux, Hansteen was led to compare it with the facts; and the result of the comparison being favourable, he was induced to study the theory of Halley, which had previously appeared to him wild and extravagant. The result of his researches, however, was favourable to that part of Halley's theory which assumes the existence of four poles and two magnetic axes. Hansteen's Memoir, which was crowned by the Danish Society, forms the groundwork of the larger volume which he published in 1817. In his fifth chapter, on the Mathematical Theory of the Magnet, he deduces the law of magnetic action from a series of experiments similar to those of Hauksbee and Lambert. Assuming that the attraction or repulsion between any two magnetic particles is directly as the intensity of the force, and inversely as some unknown power t of the mutual distance of these particles, and supposing that the magnetic intensity of any particle is proportional to some power r of its distance a from the centre of the magnet, he finds the following expression for the effect F, which a linear magnet would have upon a magnetic point situated anywhere upon the axis produced:

$$F = \int \frac{x^r\,dx}{(a-x)^t} - \int \frac{x^r\,dx}{(a+x)^t};$$

x being the length of half the axis of the linear magnet, and F (multiplied by a constant quantity, depending on the degrees of magnetism which the point and line possess) representing the force. In conducting the experiments, Hansteen placed a very sensible compass upon a horizontal table, so that the needle pointed to 0°. From beneath the centre of this needle, and perpendicular to its direction, or to the magnetic meridian, he drew a straight line upon the table, and divided it into portions, so that *ten* of them were equal to the half axis a of the artificial magnet. This magnet was then placed on the line at different distances from the needle, and the deviation of the needle from the magnetic meridian which it produced was accurately observed for each distance. Upon com-

Hansteen's researches.

paring the results, and calculating them by the formula, upon the supposition that t was 1 or 3, the differences were very great; but by making $t = 2$, the calculated and observed results agreed remarkably well, as the following table shows:

Values of a, or Distances in half Axes of the Magnet.	Values of F, or Increase of the Force.			
	Observed Values.	Calculated Values.		
		$t = 2$ $r = 1$	$t = 2$ $r = 2$	$t = 2$ $r = 3$
11	1·000	1·000	1·000	1·000
10	1·306	1·334	1·334	1·325
9	1·834	1·835	1·836	1·836
7	3·947	3·938	3·945	3·949
5	11·015	11·072	11·119	11·154
4	22·441	22·245	22·411	22·530

From this remarkable coincidence between the observed and the computed results, Hansteen concludes that "*the attractive or repulsive force with which two magnetic particles affect each other, is always directly as their intensities, and inversely as the squares of their mutual distance.*" He shows that the undetermined value of r produces almost no effect at considerable distances; and he is inclined to think that $r = 2$, or that *the absolute intensity of any magnetic particle, situated in the axis, is proportional to the square of its distance from the middle point of that axis.* Mr Hansteen has also demonstrated that *the distance from the middle of a magnet being the same, the force opposite the poles, or in the direction of the axis, is double of the force in the magnetic equator.* If a globe contains at its centre an infinitely small magnet, Hansteen shows that, *near the magnetic equator, the dip must increase twice as rapidly as the magnetic latitude, and, near the pole, half as rapidly;* and that *the increment of the dip must be equal to the alteration of the latitude of that part of the globe where the dip is* 54° 44′. Our author also states, that if the earth had only one magnetic axis, whose centre coincided with that of the earth, the lines of equal dip would coincide with those of equal intensity; but as this is far from being the case, his opinion that there are two magnetic axes becomes more probable.

The most valuable part, however, of Professor Hansteen's work is that which relates to the number, position, and revolution of the magnetic poles. Having collected all the observations of value that had been made on the variation of the needle, he proved that there were *four points* of convergence among the lines of variation, viz. a weaker and a stronger point in the vicinity of each pole of the globe. The strongest poles N, S, lie almost diametrically opposite to each other, and the same is true of the weaker poles *n, s*. These four poles he found to have a regular motion obliquely, the two northern ones N, *n*, from west to east, and the two southern ones S, *s*, from east to west. The following he found to be their periods of revolution, and their positions, in 1830:—

	Lat.	Long. from Greenwich.	Time of Revolution round each Pole of the Globe.
Pole N	69° 30′ N.	87° 19′ W.	1740 years.
Pole S	68 44 S.	131 47 E.	4609 do.
Pole *n*	85 6 N.	144 17 E.	860 do.
Pole *s*	78 29 S.	137 45 W.	1304 do.

Since the publication of these results, Professor Hansteen had access to the valuable series of magnetical observations made during the British voyages of discovery to the arctic regions; and, after a diligent comparison of them, he obtained new and more accurate determinations of the positions and periods of revolution of the four magnetic poles, but still differing so little from his previous determinations, as to give a high degree of probability to the correctness of the results. He finds from Captain Parry's observations, that in 1819 the pole N must have been situated in north lat. 71° 27′, and the time of its revolution 1890 (in place of 1740, as formerly calculated). The period of revolution of S he changed from 4609 to 4605, and that of *s* from 1304 to 1303, that of *n* remaining at 860 as before. Professor Hansteen considers N and S as the terminating points of one magnetic axis, and *n* and *s* those of the other axis; and he remarks that these two axes cross each other without intersection, or without passing through the centre of the earth. In reference to the causes of these singular changes, our author considers it possible that the illumination and heating of the earth, during one revolution about its axis, may produce a magnetic tension, as it produces the electrical phenomena. In support of his hypothesis of four poles, Professor Hansteen has shown very clearly that the changes in the variation and dip of the needle in both hemispheres may be well explained by their motion; but we cannot here enter into these details.

With the view of discovering the nature of the forces by which the phenomena of terrestrial magnetism are produced, Professor Hansteen resolved to ascertain, at different parts of the earth's surface, the *intensity* of its magnetism, and to determine the form of the lines of equal intensity, or, as he calls them, the *isodynamical magnetic lines.* By means of the same needle intrusted to different philosophers, he had observations on the number of its oscillations in a given time made in every part of Europe; and he afterwards undertook a journey to Siberia to make the observations himself in that interesting magnetical region. From these observations he deduced the following law, according to which the magnetic intensity varies with the dip of the needle:—

Magnetic Dip.	Magnetic Intensity.
0°	1·0
24	1·1
45	1·2
64	1·3
73	1·4
$76\frac{2}{3}$	1·5
81	1·6
86	1·7

Professor Hansteen's journey to Siberia was attended with secondary consequences of great value to science. The attention of the Russian government, and the Academy of Sciences at St Petersburg, was thus called to the subject of magnetism; and, on the recommendation of Baron Humboldt, the emperor liberally agreed to erect magnetic observatories in suitable stations, for determining, every *ten* years, the exact position of the *two lines of the variation* which pass through his empire.

In determining the intensity of terrestrial magnetism, Professor Hansteen observed that the time of vibration of a horizontal needle varied during the day. Graham had previously suspected a change of this kind, but his methods were not accurate enough to prove it. Hansteen, however, found that the *minimum* intensity took place between 10 and 11 A. M., and the *maximum* between 4 and 5 P. M. He concluded also that there was an annual variation, the intensity being considerably greater in winter near the perihelion, than in summer near the aphelion; that the greatest *monthly* variation was a maximum when the earth is in its perihelion or aphelion, and a minimum near the equinoxes; and that the greatest daily variation is least in winter and greatest in summer. He found also that the aurora borealis weakened the magnetic force, and that the magnetic intensity is always weakest when the moon crosses the equator. In making experiments in the round tower at Copenhagen, he found that the magnetic intensity increased regularly towards the top, where it was a maximum;[1] and having extended his observations, he obtained the general result, that at the foot of any vertical object the needle oscillates *quicker* at the *north* side of it, and *slower* at the *south* side; whereas at the upper end it oscillates *quicker* at the *south* side, and *slower* at the *north* side.

In the aerostatic ascent of MM. Gay-Lussac and Biot, they were unable to detect any change in the intensity of terrestrial magnetism at the height of 4000 metres. Saussure, however, had found that the intensity was considerably less on the Col du Géant than at Chamouni and Geneva, the difference in the levels of these places being in the one case 10,000 and in the other 7800 feet, but his observations contradict his conclusion. M. Kupffer has more recently obtained a similar result by observations on Mount Elbrouz, having found a decrease of intensity in rising 4500 feet above his first station; and he explains the result obtained by MM. Gay-Lussac and Biot by supposing that an increase of intensity was produced by the diminution of temperature. Mr Henwood, on the other hand, has made observations at the surface of Dolcoath mine, at 1320 feet beneath its surface, and on a hill 710 feet above the level of the sea, without being able to detect any difference in the intensity. To the late Captain Foster[2] we owe many valuable observations on the magnetic intensity made at Spitzbergen and elsewhere. From these he concluded, that the diurnal change in the horizontal intensity is principally, if not wholly, owing to a small change in the amount of the dip. The maximum took place at about 3h. 30′ A. M., and the minimum at 2h. 47′ P. M., its greatest change amounting to one eighty-third of its mean value. Captain Foster is of opinion that these changes have the sun for their primary agent, and that his action is such as to produce a constant inflexion of the pole towards the sun during the 24 hours, an idea which Mr Christie had previously stated.[3]

About the year 1818, Professor Barlow of Woolwich turned his attention to the subject of magnetism, with the view principally of calculating the effect of a ship's guns on the compass. In trying the effects of different iron balls, he was led to the curious facts, that there exists round every globe and mass of iron a great circle inclined to the horizon at an angle equal to the complement of the dip of the needle; that the plane of this circle is a plane of no attraction upon a needle whose centre is in that plane; that if we regard this circle as the magnetic equator, the tangent of the deviation of the needle from its north or south pole will be proportional to the rectangle of the sine of the double latitude, and cosine of the longitude; that when the distance of the needle is variable, the tangent of deviation will be reciprocally proportional to the cube of the distance; and that, all things else being the same, the tangents of deviation will be proportional to the cubes of the diameters of the balls or shells, whatever be their masses, provided their thickness exceed a certain quantity.

These results were published in the first edition of Mr Barlow's *Essay on Magnetic Attractions*; but in the second edition of that work, he has published some curious results respecting the relative magnetic power of different descriptions of iron and steel, and on the effect of temperature on the quality and quantity of the attractive power of iron. The results of the first of these series of experiments were as follow, the numbers expressing the proportional magnetic power of the different descriptions of iron and steel.

History.

Mr Barlow's discoveries.

Malleable iron	100	Shear steel, hard	53
Blistered steel, soft	67	Cast iron	48
Blistered steel, hard	53	Cast steel, soft	74
Shear steel, soft	66	Cast steel, hard	49

In his experiments on the effects of temperature, Mr Barlow found that every kind of iron and steel possessed a greater capacity for the development of its magnetism when softened by heat than when cold; from which he concludes that its complete development when cold is prevented only by the hardness or resisting power of the metal. At a *white* heat he found that iron lost entirely its magnetic power, a result apparently inconsistent with the preceding conclusion; but, what was a still more extraordinary circumstance, when the *white* heat, at which there was no magnetism, began to subside into a *bright red*, or *red* heat, an *attractive* power showed itself, the *reverse* of what it had when cold; and after it had passed through these two shades of colour, it resumed the same attractive power which it had when cold, the passage from the negative attraction of red passing into the positive attraction of the cold metal at the point of a red heat, the maximum, however, taking place at a blood-red heat.

Mr C. Bonnycastle.

The experimental laws of attraction of an iron shell or sphere, obtained by Mr Barlow, were first examined theoretically by Mr Charles Bonnycastle, who deduced them mathematically from the theory of Æpinus, which supposes the two magnetic fluids to be accumulated in the poles of magnets. This theory, however, led to some improbable consequences, and therefore Mr Barlow was induced to adopt that of Coulomb and Biot, with the modification, *that the magnetic power all resides on the surface of iron bodies, and is independent of the mass;* a modification which enabled Mr Barlow to obtain a general analytical expression of the disturbing power of an iron ball at its surface, as compared with that of the earth, and from which he deduced theoretically all his experimental laws.

These important discoveries enabled Mr Barlow to invent a most ingenious method of correcting the error of the compass, arising from the attraction of all the iron on board ships. This source of error had been noticed by Mr Wales, Mr Downie in 1794, and by Captain Flinders; but it is to Mr Bain[4] that we owe the distinct establishment and explanation of this source of error. As a hollow shell of iron about four pounds in weight acts as powerfully at the same distance as a solid iron ball of 200 pounds weight, Mr Barlow happily conceived that a plate of five or six pounds weight might be made to represent and counteract the amount of the attraction of all the iron on board a vessel, and therefore leave the needle as free to obey the action of terrestrial magnetism as if there were no iron in the ship at all. After this ingenious contrivance had been submitted to the admiralty, it was tried in every part of the world; and even in the regions which surround the magnetic pole, where the compass becomes useless, it never failed to indicate the true magnetic direction when the connecting plate was properly applied. At Port Bowen, where the dip is 88°, and the magnetic intensity which acts upon a horizontal needle extremely weak, the azimuth compass on board Captain Parry's ship gave the very same variation as that observed on shore. "Such an invention as this," says Captain Parry, "so sound in principle, so easy of application, and so universally beneficial

Mr Barlow's discoveries.

in practice, needs no testimony of mine to establish its merits; but when I consider the many anxious days and sleepless nights which the uselessness of the compass in these seas had formerly occasioned me, I really should have esteemed it a kind of personal ingratitude to Mr Barlow, as well as great injustice to so memorable a discovery, not to have stated my opinion of its merits, under circumstances so well calculated to put them to a satisfactory trial." For this beautiful invention, the Board of Longitude conferred upon Mr Barlow the highest reward of L.500; and the Emperor of Russia, who was never inattentive to the interests of science, sent him a fine gold watch and a rich dress chain, for the same contrivance.

Magnetism of rotation.

A series of beautiful discoveries was made about this time by M. Arago, Mr Christie, and Mr Barlow, on the influence of rotation on bodies both magnetic and non-magnetic. Mr Barlow, so early as 1818 or 1819, had found, that when a plate of iron was made to turn upon its centre, different parts of its circumference had different degrees of magnetic action on the compass; but here there was no effect discovered as due to rotation. In 1821, Mr Christie, in a series of experiments on iron plates, not only found that different parts in the circumference of the same plate had different attracting powers; but *that the same part had a different influence, according as the same plate was made to revolve to the right or left hand.* Mr Christie therefore discovered that there was a *deviation due to rotation*, and that magnetical effects were produced which were nearly independent of the velocity of rotation, and which continued after the rotation had ceased. When the rotation was very rapid, the forces exerted upon the needle were always in the same direction as the forces derived from the slowest rotation, and which continue to act after the rotation has ceased, the former being to the latter nearly as three to two. From all the observations made by Mr Christie, he considers that the direction of the magnetic polarity acquired by rotation, whether at right angles to the line of the dip or not, has always a reference to the direction of the terrestrial magnetic force; and he infers that this magnetism is communicated to it from the earth. "It does not therefore appear from this," says Mr Christie, "that a body can become polarised by rotation alone, independently of the action of another body; so that, if from these experiments we might be led to attribute the magnetic polarity of the earth to its rotation, we must at the same time suppose a source from which magnetic influence is derived. Is it not, then, possible that the sun may be the centre of such influence, as well as the source of light and heat, and that, by their rotation, the earth and other planets may receive polarity from it?" When these experiments were repeated at Port Bowen in 1825 by Captain Foster, the phenomena were exhibited on a more striking scale.

Mr Christie.

Mr Barlow.

In December 1824, Mr Barlow began a series of experiments, with the view of ascertaining whether magnetism, as produced by various processes with iron, could be excited or disturbed by rapid rotation. They were completed in January, but their publication was delayed till June, that an account of them might appear along with those of Mr Christie above mentioned. Mr Barlow's first experiments were made on a 13-inch shell attached to a lathe turned by a steam-engine, the mean speed of which was about 640 revolutions in a minute. The deviation of a needle exposed to its action increased with the velocity, and remained constant while the velocity continued constant, the needle always returning exactly to its original position the moment the motion of the ball ceased. This, therefore, is a phenomenon different from that observed by Mr Christie; a temporary effect wholly dependent on the velocity of rotation, whereas that observed by Mr Christie was permanent, and nearly independent of the number of revolutions. In examining the direction of the new force impressed upon the iron shell, he found it to be in every case equivalent to a polarisation at right angles to the axis of rotation.

Discoveries of M. Arago.

Previous to the publication of these experiments, and without any knowledge of them, M. Arago had made the remarkable discovery, that if plates of copper and other substances are put into rapid rotation beneath a magnetised horizontal needle freely suspended, the rotatory plate will first cause the needle to deviate from its true direction; and by increasing the velocity, the deviation will increase, till the needle passes the opposite point, when it will continue to revolve, and at last with such velocity that the eye is unable to distinguish it.

M. Arago was led to this beautiful discovery by a previous series of experiments of great interest. He found that a magnetic needle oscillating above or near any body whatever, such as a plate of metal or a surface of water, gradually oscillated in arcs of less and less amplitude, as if it had been placed in a resisting medium; and, what was particularly remarkable, the number of oscillations performed in a given time was not changed. This curious fact was announced to the Academy of Sciences in Paris on the 22d of November 1824; and he was hence conducted to the still more remarkable discovery of the effects of rotation which we have already mentioned.

Seebeck.

M. Seebeck of Berlin repeated the experiments of M. Arago on the influence of plates of metal and other substances in diminishing the amplitude of oscillation; but we must reserve our account of them till we come to the chapter on that subject.

Messrs Babbage and Herschel.

The experiments of M. Arago on the rotation of metallic plates were described and repeated by M. Gay-Lussac in London in the month of March or April 1825; and they excited so much attention, from their connection with the effects observed by Mr Barlow, that Mr Babbage and Mr Herschel immediately erected an apparatus for repeating them. In their first trial, the deviation of the needle did not exceed 10° or 11° with a revolving plate of copper. In order to enlarge the visible effect, they reversed the experiment, in order to try whether discs of copper and other non-magnetic substances might not be set in motion if suspended over a revolving magnet. A horse-shoe magnet, capable of lifting twenty pounds, was made to revolve rapidly about its axis of symmetry placed vertically. A circular disc of copper, six inches in diameter and one twenty-fifth of an inch thick, was suspended centrally over it, by a silk thread just capable of supporting it. A sheet of paper being interposed, and the magnet set in motion, the copper began revolving in the same direction, at first slowly, but with an accelerating velocity. On reversing the motion of the magnet, the velocity of the copper was destroyed gradually. It stopped for an instant, and then immediately began to revolve in the opposite direction. Screens of paper, glass, wood, copper, tin, zinc, lead, bismuth, were interposed betwixt the magnet and the copper, but they exerted no sensible interceptive power. But when tinned iron plate was interposed, the magnetic influence was greatly diminished by one plate, and almost annihilated by two thicknesses of it. A piece of iron connecting the two poles of the revolving magnet produced the same effect. The substances in which signs of magnetism were developed by the revolving magnet were copper, zinc, silver, tin, lead, antimony, mercury, gold, bismuth, and carbon in the state in which it is precipitated from carburetted hydrogen in gas-works. By getting plates of different metals cast in the same mould, they found that the proportional intensity of magnetic action for each respectively was as follows:

Zinc	1·11	Lead	0·25
Copper	1·00	Antimony	0·01
Tin	0·51	Bismuth	inappreciable.

M. Arago had observed the very remarkable fact, that if the disc of copper be cut from the circumference towards the centre, like radii, but without taking away the metal, the action upon the needle is greatly diminished. After verifying this result, Messrs Babbage and Herschel ascertained that re-establishing the metallic contact with other metals, restored, either wholly or very nearly, the original power of the plate, even though the soldering metal had a very feeble magnetic power. The law of the force, with a decrease of distance, they found to vary between the square and the cube. "The rationale," says Messrs Babbage and Herschel, "of these phenomena, as well as of those observed by Mr Barlow in the rotation of iron, which form only a particular case (though certainly the most prominent of any) of the class in question, seems to depend on a principle which, whether it has or has not been before entertained, or distinctly stated in words, it may be as well, once for all, to assume here, as a *postulatum*, viz. that *in the induction of magnetism, time enters as an essential element, and that no finite degree of magnetic polarity can be communicated to or taken from any body whatever, susceptible of magnetism, in an instant.*

The preceding results were verified by Mr Christie, who found, that when a thick plate of copper revolved under a small magnet, the force which deflected the needle varied inversely as the fourth power of the distance; but when the copper discs were small, and the magnets large, the power of the distance was between the square and the cube; when the plates were of different weights, the force was nearly in the ratio of the weights at small distances, but at smaller distances it varied in a higher ratio.

The discovery of two poles of maximum cold on opposite sides of the north pole of the earth, which was announced by Sir David Brewster in 1820, led him and other authors to the opinion that there might be some connection between the magnetic poles and those of maximum cold. "Imperfect," says he, "as the analogy is between the isothermal and magnetic centres, it is yet too important to be passed over without notice. Their local coincidence is sufficiently remarkable, and it would be to overstep the limits of philosophical caution to maintain that they have no other connection but that of accidental locality; and if we had as many measures of the mean temperature as we have of the variation of the needle, we might determine whether the isothermal poles were fixed or moveable." And he concludes his paper on the mean temperature of the globe with the following paragraph: "Having thus endeavoured to establish a new law of the distribution of heat over the surface of the globe, it might be no uninteresting inquiry to investigate the causes which have modified in so remarkable a manner the influence of the solar rays. The subject, however, is too comprehensive and too hypothetical to be discussed at present. How far the general form and position of the continents and seas of the northern hemisphere may disturb the natural parallelism of the isothermal lines to the equator,—to what extent the current through Behring's Strait, transporting the waters of warmer climates across the polar seas, may produce a warm meridian in the direction of its motion, and throw the coldest parts of the globe to a distance from the pole,—whether or not the magnetic, or galvanic, or chemical poles of the globe (as the important discoveries of Mr Oersted entitle us to call them), may have their operations accompanied with the production of cold, one of the most ordinary effects of chemical action,—or whether the great metallic mass which crosses the globe, and on which its magnetic phenomena have been supposed to depend, may not occasion a greater radiation of heat in those points where it developes its magnetic influence,—are a few points which we may attempt to discuss when the progress of science has accumulated a greater number of facts, and made us better acquainted with the superficial condition as well as the internal organization of the globe."[1]

The two poles of maximum cold, which will likely perform an important part in the future history of terrestrial magnetism, are situated, according to Sir David Brewster, as follows, according to the best observations made both near them and at a distance. The American pole is situated in latitude 73° north, and longitude 100° west from Greenwich, a little to the east of Cape Walker; and the Asiatic pole in latitude 73° north, and longitude 80° east, between Siberia and Cape Matzol on the Gulf of Oby. Hence the two warm meridians will be in west longitude 10° and east longitude 170°, the latter passing through Lord Mulgrave's range, and the former between St Helena and Ascension Island. The two cold meridians, or those which pass through the poles of maximum cold, will be in west longitude 100° and east longitude 80°, the latter passing near Mexico and through Bathurst Island, and the former through Colombo in Ceylon, Berar in Hindustan, and crossing the Oby a little to the west of Narym in Siberia. The following is the formula which the same author has given for the mean temperature at any point of the globe, T being the mean temperature required, t the maximum equatorial temperature, τ the minimum temperature at each of the cold poles, and δ, δ' the distances of the place from the two cold poles.

$$T = (t - \tau)\,(\sin.^n \delta \,.\, \sin.^n \delta') + \tau.$$

The distances δ, δ' are found from the formulæ

$$\cos. \delta = \frac{\cos. L\,(\cos. L - \theta)}{\cos. \theta} \text{ and}$$

$$\text{tang. } \theta = \cos. M \text{ tang. } L\,;$$

in which L is the colatitude of the pole of maximum cold, l the colatitude of the place, and M the difference of longitude between the place and the pole of maximum cold. The values of t and τ have been determined with considerable accuracy, t being nearly 82°·8 Fahrenheit, and τ from 0° to $-3\frac{1}{2}$°. The exponent n is nearly $\frac{5}{8}$ths, but future observations may induce us to increase or diminish it.

Now it is a remarkable circumstance that the same formula, *mutatis mutandis*, expresses the magnetic intensity of magnetism at any point of the earth's surface, the intensity at the two magnetic poles being supposed equal. If we call S the maximum number of seconds in which any number n of oscillations are performed which takes place at the island of St Thomas on the west coast of Africa, and s the minimum number of seconds in which n oscillations are performed which takes place at the magnetic poles, then the intensity I will be

$$I = (S - s)\,(\sin.^n \delta \sin.^n \delta') + s,$$

δ and δ' being determined by the formulæ already given, adopting the position of the poles in the preceding page. The values of S and s, according to Captain Sabine and Hansteen, will be about 370″ and $262\frac{1}{2}$″. This formula will give for the *isodynamical lines*, or those of equal intensity, a series of returning curves of the nature of Lemniscates, almost similar to those drawn by Captain Sabine, and given in a future figure, and exactly like the polar isothermal lines.

The connection thus indicated between the heat and the magnetism of the earth has been studied by succeeding authors, and the general principle has been adopted by many distinguished philosophers. Dr Traill expressed the opinion, "that the disturbance of the equilibrium of the temperature of our planet by the continual action of the sun's rays on its intertropical regions, and by the polar ices, must convert the earth *into a vast thermo-magnetic appara-*

Connection between the temperature and magnetism of the globe.

tus;" and "that the disturbance of the equilibrium of temperature even in stony strata may elicit some degree of magnetism." Mr Christie thinks it "not improbable that difference of temperature may be the primary cause of the polarity of the earth, though its influence may be modified by other circumstances." M. Ampère, who ascribes magnetism to transverse electrical currents, thinks that the strata of our globe may form considerable galvanic arrangements, and that the electric currents may be affected by the rotation of the earth. M. Oersted remarks, in a recent treatise on thermo-electricity, "that the most efficacious excitation of electricity upon the earth appears to be produced by the sun producing daily evaporation, deoxidation, and heat, all of which excite electrical currents." After stating that the sun daily produces electric currents, and these currents magnetism, he observes, that "thus the earth seems to have a *constant magnetic polarity*, produced in the course of time by the electrical currents which surround it, and a *variable magnetism*, produced immediately by the same current." As the sun produces different effects on water and solid bodies, Oersted supposes that the intensity will vary in the same parallel, and the direction of the needle will be oblique to the equator, in consequence of the lines of equal electro-magnetic intensity being twice bent by the influence of the two great masses of continent. "The yearly and daily change," he observes, "must occasion yearly and daily variations. As to the variations comprehended in greater periods, we might perhaps attribute them to a *motion of the coolest points in such continents*, which, it appears, cannot remain the same for ever, because the currents of warmer air must principally be directed to such points." Analogous views have been recently stated by M. Kupffer, in a memoir read in 1829 to the Russian Academy, in which he adopts explicitly Sir David Brewster's opinions of the existence of two cold poles distant from the pole of revolution. "But this distribution of temperature," says he, "*appears also to have a great influence on the distribution of the intensity of terrestrial magnetism.* This would no doubt be the case if it is true, as I have tried to show in another memoir, that terrestrial magnetism resides at the surface of the globe. We have here the choice between *two* hypotheses; either the earth should be considered as a magnet existing by itself, and then the intensity of its magnetism will be the inverse of its temperature; or it receives its influence from without, and is only like a piece of soft iron, to which the presence of a distant body communicates magnetism, and then the intensity of its magnetism will increase with its temperature. Though the first of these hypotheses has been hitherto generally adopted, yet the second acquires some probability from the discovery of the magnetic influence of the solar rays, and of the known relation between the diurnal variations of the declination of the needle and the course of the sun." The connection between the poles of maximum cold and those to which the isodynamical magnetic lines are related, is considered by Dr Dalton as a probable supposition. "If the idea," says he, "suggested by Sir David Brewster in the Transactions of the Royal Society of Edinburgh, vol. ix. 1821, be correct (and there seems great reason to believe it to be so), namely, *that there are two poles of greatest cold in the northern hemisphere*, the above observation will enable us to see the natural cause of this remarkable fact. The lands within the arctic circle, in the absence of the sun, must depend upon the south-west winds from the two great oceans for their winter heat. Those parts of the eastern and western continents which are most remote from the ocean, as measured along the curvilinear tracts of the current of air, must receive that air in great measure deprived both of its vapour and its temperature. Accordingly it is found that the temperature of the north-east parts of such continents exhibits the extreme of cold. Probably a latitude of 75° north, and a longitude of 90° east and 90° west, would be found nearly equally cold, and to exceed any other place on the surface of the globe in this respect; and it would be a curious coincidence if Professor Hansteen's two supposed northern magnetic poles should be found in the same positions as the two poles of extreme cold."[1]

Magnetism of the solar rays.

In a general history of magnetical discoveries, it may be proper to take some notice of the very curious experiments which have been made respecting the influence of the solar rays in the production of permanent magnetism, although, according to the generally received opinion, the existence of such an influence has not been established; but if the propriety of doing this had been doubtful, the observation just made by M. Kupffer, as connecting this supposed property of violet light with terrestrial magnetism, would have removed the doubt. Dr Morichini, an eminent physician in Rome, was the first who announced it as an experimental fact, that an unmagnetised needle could be rendered magnetic by the action of the violet rays of the sun. His experiments were successfully repeated by Dr Carpi at Rome, and the Marquis Ridolfi at Florence; but M. d'Hombre Firmas at Alais in France, Professor Configliachi of Pavia, and M. Bérard of Montpellier, failed in obtaining decided magnetic effects from the violet rays. In 1814 Dr Morichini exhibited the actual experiment to Sir Humphry Davy, and in 1817 Dr Carpi showed it to Professor Playfair. A few months after Sir Humphry witnessed the experiment, the writer of this article met him at Geneva, and learned from him the fact, that he had paid the most diligent attention to one of Morichini's experiments, and that he saw, with his own eyes, an unmagnetised needle rendered magnetic by violet light. The following account of the experiment made by Dr Carpi was given to us verbally by Professor Playfair, who approved of the statement of it which we drew up at the time. "The violet light was obtained in the usual manner, by means of a common prism, and was collected into a focus by a lens of a sufficient size. The needle was made of soft wire, and was found upon trial to possess neither polarity nor any power of attracting iron filings. It was fixed horizontally upon a support, by means of wax, and in such a direction as to cut the magnetic meridian at right angles. The focus of violet rays was carried slowly along the needle, proceeding from the centre towards one of the extremities, care being taken never to go back in the same direction, and never to touch the other half of the needle. At the end of half an hour after the needle was exposed to the action of the violet rays, it was carefully examined, and it had acquired neither polarity nor any force of attraction; but after continuing the operation twenty-five minutes longer, when it was taken off and placed on its pivot, it traversed with great alacrity, and settled in the direction of the magnetical meridian, with the end over which the rays had passed turned towards the north. It also attracted and suspended a fringe of iron filings. The extremity of the needle that was exposed to the action of the violet rays repelled the north pole of a compass-needle. This effect was so distinctly marked as to leave no doubt in the minds of any who were present, that the needle had received its magnetism from the action of the violet rays." In this state of the subject, Mrs Somerville made some simple and well-conducted experiments, which seemed to set the question at rest, from the distinct and decided

[1] *Meteorological Observations and Essays*, second edition, 1834, p. 215.

character of the results. A sewing needle, an inch long, and devoid of magnetism, had one half of it covered with paper, and the other exposed to the violet rays of the spectrum, five feet distant from the prism. In two hours it acquired magnetism, the exposed end exhibiting north polarity. The *indigo* rays produced an equal effect, and the *blue* and *green* the same in a less degree. The *yellow*, *orange*, and *red* rays had no effect even after three days' exposure to their action. Pieces of blue watch-springs received a higher magnetism. When the sun's light fell upon the exposed end through blue coloured glass, or through *blue* or *green* riband, the same magnetic effects were produced.

The experiments of Mr Christie, an account of which was read to the Royal Society a short time before Mrs Somerville's, confirmed her results to a certain degree, by a different mode of observation. He found that the compound solar rays possessed magnetic influence, and exhibited it in their effect of diminishing the vibrations of magnetised and unmagnetised steel needles, and also needles of copper or of glass, by making them oscillate in the sun's white ray. Mr Christie, however, has recently remarked, that as his experiments have not succeeded on repetition by Mr Snow Harris, when made in a vacuum, his results must have been owing to currents of air. In justice to Mr Christie, however, we must mention, that Professor Zantedeschi repeated Mr Christie's experiments at Pavia, under an Italian sun, with a needle a Paris foot long, and obtained a striking result. This needle, when drawn from its position of equilibrium, through an area of 90°, performed four oscillations in 30″, the last of which had a semiamplitude of 70°. In the solar rays it performed in 30″ four oscillations, the last of which had only a semiamplitude of 60°. When he exposed to the sun the north pole, the semiamplitude of the last oscillation was 6° less than that of the first, while by exposing the south pole this last oscillation became greater than the first. The experiments of Baumgartner and Barlocci tended to confirm these results. The former found that iron wires polished on a part of their length are magnetised by white solar light, exhibiting a north pole on the polished part; and the latter has shown that an armed natural loadstone, which carried $1\frac{1}{2}$ Roman pound, exhibited, after three hours' exposure to the strong light of the sun, an increase of energy equivalent to 2 ounces or $\frac{1}{6}$th of a pound, while another larger one, which carried 5 pounds 5 ounces, had its strength nearly doubled by two days' exposure. Zantedeschi tried an artificial horse-shoe loadstone, which carried $13\frac{1}{2}$ ounces; after three days' exposure to the sun it carried $3\frac{1}{2}$ ounces more, and by continuing its exposure its power increased to 31 ounces. An oxidated magnet gained most power, and a polished one none. He found also that the north pole of a loadstone exposed to the sun's rays concentrated by a lens acquires strength, while its south pole, similarly exposed, loses it.

Notwithstanding all these results, the general opinion seems now to be, that light does not exercise any decided effect in producing magnetism. The experiments of MM. P. Ries and Moser were made with needles both polished and oxidated, and also with wires half-polished; and polarised as well as common light was made to fall upon them in a concentrated state, but no decided effect upon their number of oscillations could be observed; and they state that they think themselves justly entitled *to reject totally a discovery which, for seventeen years, has at different times disturbed science.*

In 1827, Mr Snow Harris communicated to the Royal Society of Edinburgh his *Experimental Inquiries concerning the Laws of Magnetic Forces*, made with a beautiful and accurate instrumental apparatus, invented by the author for examining the phenomena of induced magnetism. With this apparatus he found that the magnetic development in masses of iron by induction is, *cæteris paribus, directly proportional to the power of the inductive force, and inversely as the distance;* and that the forces which magnets develope in a mass of iron at a given distance, within certain limits, may be taken as a fair measure of their respective intensities. From another series of experiments he has shown, that the absolute force of attraction exerted between a magnet and a piece of iron, varies with the power of the magnet, and consequently with the force induced in the iron, *cæteris paribus;* and that when the force induced in the iron is a constant quantity, while its distance from a temporary or permanent magnet is variable, *the absolute force varies with the distance.* This result was not only apparent when the magnetic force was varied by induction, but was also satisfactorily shown when varied by magnets of which the relative powers of induction were previously ascertained. Mr Harris made a number of nice experiments on the absolute force of attraction and repulsion between two magnetised bodies, which he found to be in the inverse ratio of the square of the distance. When, in the case of attraction, the magnets, however, were nearly approximated in relation to their respective intensities, the increments in the forces began to decline, and in some instances at near approximations the absolute force was in the simple inverse ratio of the distance. In the experiments with the repelling poles, the deviations from the regular force were still more considerable, and, what is curious in this case, the force became less and less, until the polarity of the weaker magnet appeared to be so counteracted by induction, *that the repulsion was at length superseded by attraction.* Mr Harris next proceeded to determine the law according to which the forces are developed in different points of the longitudinal magnetic axis between the centre and poles of a magnet, and he found that it varied directly as the square of the distance from the magnetic centre; a law which is uniform in bars of steel regularly hardened and magnetised throughout. This law of distribution is exactly the same as that which has been given by Hansteen.

Mr Harris has also published other two memoirs in the Philosophical Transactions for 1831, the first *On the Influence of Screens in arresting the progress of Magnetic Action*, and the second *On the Power of Masses of Iron to control the Attractive Force of a Magnet*, of both of which some account will be found in a subsequent section. In his latest paper, *On the Investigation of Magnetic Intensity by the Oscillations of the Magnetic Needle*, he exposed an oscillating magnetic bar to a bright sunshine; and though he observed the effect observed by Mr Christie, which that philosopher ascribed to the influence of the sun's rays, yet he found that they all disappeared when the needle was made to oscillate in an exhausted receiver.

M.Haldat.
A. D. 1830.

M. Haldat of Nancy communicated, in 1830, to the society of that city, the results of some interesting researches on the incoercibility of the magnetic fluid, or its power of exerting its influence through all bodies, even the most dense; a property which is not possessed by light, heat, or electricity. In this research he adopted various methods of observation, and interposed a great variety of substances; and from the numerous experiments which he made, he has drawn the following conclusions: 1. That the agent or fluid by which the magnetic phenomena are explained is incoercible in the present state of the science; 2. that iron, considered as presenting an exception to this law, coerces the magnetic influences only by acquiring itself the magnetic state; 3. that incandescence does not give to bodies the power of coercing the magnetic influence. In a previous memoir, M. Haldat had obtained some interesting results on the production of magnetism by friction. He found that all hard bodies may, by means of friction, assist in the decomposition of the magnetic fluid, if their action is promoted by the combined action of magnets which, by themselves, are incapable of producing it. If a piece of soft wire, for example, four inches long, and 1-25th of an inch in diameter, is placed horizontally between two bar-magnets, with their opposite poles facing each other, and at such a distance that the wire cannot be magnetised, it will receive distinct magnetism by friction with all hard bodies, such as copper, brass, zinc, glass, hard woods, &c. M. Haldat employed the ingenious process of M. Gay-Lussac, of magnetising soft iron by torsion, in neutralising the wires before they were magnetised. If they are twisted after receiving magnetism, they will preserve the magnetism which they had received before torsion; but if, after being twisted, they are twisted in an opposite direction, they will become perfectly neutral.

M. Haldat likewise made some interesting experiments on the effect of the coercive force in steel on the magnetism produced by rotation, and he found that the force with which a revolving steel disc dragged round a magnetic needle was in the inverse ratio of the coercive force of the steel. When the discs were not hot, they had the same effect as those at the ordinary temperature. We owe also to M. Haldat an interesting paper on magnetic figures. Figures of any kind, when traced by the pole of a magnet on a plate of steel, are rendered visible by sifting upon the invisible tracings filings of steel, which arrange themselves in the most beautiful manner along the outlines of the figure which has been traced.

M. Quetelet.
A. D. 1830.

A series of very interesting experiments have been recently published by M. Quetelet of Brussels, *On the successive degrees of Magnetic Force which a Steel Needle receives during the multiple frictions which are employed to magnetise it.* These experiments were made principally before 1830, but they were not given to the public till 1833. The following are the general results which were obtained by the author.

1. When a needle or bar that had never been magnetised, is magnetised to saturation by the method of separate contact, the magnetic force acquired is a maximum in relation to the forces which can be given to the same needle or bar by the subsequent reversals of its poles.

2. The magnetic force which a needle can acquire becomes weaker in proportion as the reversal of its poles, has been multiplied. The series of frictions which tend to bring back the poles to their primitive state are more efficacious than the others.

3. This difference between the forces which the needle acquires after the successive reversal of its poles, goes on continually diminishing, and converges towards a limit. It depends in general on the size of the needle in relation to that of the rubbing bars, as well as in its force of coercion.

4. A needle cannot receive all the magnetic force which it can acquire, if the frictions do not take place over all its surface; this becomes particularly sensible in the reversal of the poles.

5. The rubbing bars give (*cæteris paribus*) to bars of the same dimensions as themselves a magnetic force equal to that which they possess, and in bars of different dimensions the forces acquired are as the cubes of their homologous dimensions. The last part of this proposition was long ago established by Coulomb.

6. When we rub magnetic bars with other bars weaker than themselves, the force of the first diminishes in place of increasing; and it appears that the force becomes that which those latter bars would be capable of giving at the first by directly magnetising them.

7. The relation which exists between the forces which a needle or a bar receives by successive frictions, and the number of these frictions, may be expressed by an exponential formula of three constants.

One of these constants appears to change its value with the size of the bars which are magnetised, at least while these bars have a magnitude which does not exceed that of the rubbing bars, and while they are of the same quality of steel.

In this way we know beforehand the successive degrees of force which a bar takes at each friction, if we have previously determined the law of these augmentations for the same rubbing bars, and for any other bar which we get to serve as the modulus. If the bar which is rubbed has begun to be magnetised, we must calculate first the number of frictions to which this force corresponds, in order to be able to assign the rank of the subsequent frictions, and the magnitude of the corresponding magnetical forces.

8. When the rubbing bars are greater than the bar to be magnetised, from the first complete friction the force of magnetism is very nearly one half of the force which the magnetised bar will finally possess.

After the twelfth complete friction, the magnetic force differs little from that which the rubbing bars can communicate.

We owe also to M. Quetelet two interesting memoirs on the magnetic intensity of different places in Switzerland, Italy, Germany, and the Low Countries.

Magnetic influence of the aurora borealis.

The influence of the aurora borealis on the magnetic needle, which was observed by Hiorter at Upsal in 1741, and by Wargentin in 1750, had long induced philosophers to regard it as a magnetic phenomenon; and this was greatly confirmed by the fact that the south end of the dipping needle points to that part of the heavens to which the rays of the aurora appear to converge. "The aurora borealis," says Dr Robison, "is observed in Europe to disturb the needle exceedingly, sometimes drawing it several degrees from its position. It is always observed to increase its deviation from the meridian, that is, an aurora borealis makes the needle point more westerly. This disturbance sometimes amounts to six or seven degrees, and is generally observed to be greatest when the aurora borealis is most remarkable.

Robison.

"This is a very curious phenomenon, and we have not been able to find any connection between this meteor and the position of a magnetic needle. It is to be observed, that a needle of copper or wood, or any substance besides iron, is not affected. We long thought it an electric phenomenon, and that the needle was affected as any other body balanced in the same manner would be; but a copper needle would then be affected. Indeed, it may still be doubted whether the aurora borealis be an electric phenomenon. They are very frequent and remarkable in Sweden, and yet Bergman says that he never observed any electric symptoms about them, though in the mean time the magnetic needle was greatly affected.

"We see the needle frequently disturbed, both from its general annual position, and from the change made on it by the diurnal variations. This is probably the effect of auroræ boreales which are invisible, either on account of thick weather or daylight. Van Swinden says he seldom or never failed to observe auroræ boreales immediately after any anomalous motion of the needle; and concluded that there had been one at the time, though he could not see it. Since no needle but a magnetic one is affected by the aurora borealis, we may conclude that there is some natural connection between this meteor and magnetism. This should farther incite us to observe the circumstance formerly mentioned, viz. that the south end of the dipping needle points to that part of the heavens where the rays of the aurora appear to converge. We wish that this were diligently observed in places which have very different variations and dips of the mariner's needle."

Van Swinden.

Dr Dalton.

A valuable series of observations on the influence of the aurora borealis on the magnetic needle was made by Dr

Dalton, at Kendal and Keswick, during seven years from May 1786 to May 1793, and has been published in his Meteorological Observations and Essays, which appeared in 1793. During these observations he noticed the effect which they produced on the magnetic needle, and he was thus led to study the phenomena of the aurora, and to establish beyond a doubt the relation of all its phenomena to the magnetic poles and equator. His views and speculations on this subject we shall detail at some length in a future part of this article; but we shall at present give our readers a specimen of the observations which he made on the magnetic needle during the changes of an aurora.

Feb. 12. The aurora appeared at Kendal after 6h. P. M. flaming over two thirds of the hemisphere. The beams converged to a point in the magnetic meridian, about 15° or 20° to the south of the zenith. The following were the changes which he observed in the needle and in the aurora:—

Time. *h.*	*m.*	Variation. °	′	Observations.
5	0 P. M.	25°	5′	west.
6	35	24	49	altitude of the clear space south 35°.
6	42	24	55	altitude of ditto 20°, streamers bright, east.
6	50	25	0	streamers bright and active all over the illuminated part.
7	2	25	28	
7	5	25	12	
7	10	24	40	disappeared in the west, active east.
7	20	24	35	active about the zenith, light faint.
7	35	24	45	light faint.
8	0	24	45	strong light northward.
8	10	24	45	a large uniform still light covering half the hemisphere, with flashes now and then.
8	35	24	47	
9	15	24	43	streamers north-west, bright east; clouds.
9	20	24	43	the aurora bursting out openly.
9	30	24	50	as fine and large a display of streamers as has appeared this evening.
10	0	24	55	
10	15	24	57	the light growing fainter and fainter.
10	35	24	40	

In these observations, the deviation produced by the aurora was 53′. In some cases during the prevalence of auroras Dr Dalton did not observe any perceptible disturbance of the needle.

Professor Hansteen observes, that large extraordinary movements of the needle, in which it traverses frequently with a shivering motion an arc of several degrees on both sides of its usual position, are seldom, perhaps never, exhibited, unless when the aurora borealis is visible; and that this disturbance of the needle seems to operate at the same time in places the most widely separate. "The extent of such extraordinary movements," he adds, "may, in less than twenty-four hours, amount to 5° or $5\frac{1}{2}$°. In most cases, the disturbance is also communicated to the dipping needle; and so soon as the crown of the aurora quits the usual place (the points where the dipping needle produced would meet the sky), the instrument moves several degrees forward, and seems to follow it. After such disorders, the mean variation of the needle is wont to change, and not to recover its previous magnitude till after a new and similar disturbance."

M. Arago.

From an extensive series of accurate observations made by M. Arago at Paris since 1818, the needle was almost invariably found to be affected by auroræ that were seen in Scotland; and so striking was the connection between the two classes of facts, that the existence of the aurora could be inferred from the derangements of the needle. M. Arago has likewise discovered, that, early in the morning, often ten or twelve hours before the aurora is developed in a very distant place, its appearance is announced by a particular form of the curve which exhibits the diurnal variation of the needle, that is, by the value of the morning and evening maxima of elongation. From a number of corresponding observations on the hourly declination made by M. Arago and M. Kupffer, who established at Kasan, near the eastern limit of Europe, one of Gambey's compasses, similar to that used at Paris, these philosophers were convinced that, notwithstanding a difference of longitude of above 47°, the disturbances produced upon the needle by the aurora took place at the same instant. It is a curious fact, however, and one yet unexplained, that during the frequent occurrence of the aurora at Port Bowen, Captain Foster did not observe any peculiar changes in the direction of the needle, although, from his great proximity to the magnetic pole, the diurnal change sometimes amounted to 4° or 5°; and, under such circumstances, the influence of the aurora ought to have been particularly conspicuous. Mr Christie is of opinion that the direction of the needle may be influenced by the electrical state of the clouds; and he found it to be so in a very distinct experiment which he made for the purpose. Captain Sir Everard Home had observed the same effect produced during thunder storms; and, in two instances, he found that a needle came sooner to rest during a thunder storm than it had done either previous or subsequent to it, the number of oscillations having been reduced in one case from 100 to 40, and in another from 200 to 120.

Magnetic influence of the aurora.

Captain Foster.

Captain Home.

Captain Back.

During the late journey of Captain Back to the polar regions in 1833, 1834, and 1835, he found that the needle was generally affected by the aurora; and on one occasion the deviation which it produced was 8°. "For nearly a month, however" (previous to the 7th January 1834), he remarks, "the needle had not been perceived to be affected by the aurora, which, it may be proper to observe, was always very faint, apparently high, and generally confined to one point of the heavens.[1] Captain Back repeatedly observed, that when the aurora was concentrated in individual beams, the needle was powerfully affected; but that it generally returned to its mean position when the aurora became generally diffused. On several occasions the needle was restless, and exhibited the vibrating action produced by the aurora when this motion was not visible; and Captain Back states that he could not account for this, except by supposing the invisible presence of the aurora in full day.

Mr David Lyon.

The only metals which were supposed to have a distinct and decided power, and were therefore called magnetic metals, are iron, nickel, and cobalt. Mr David Lyon[2] has lately endeavoured to show that these metals resemble one another, not only in their principal qualities, but in the numerical values of their qualities; and he adds, that whilst these three magnetic substances have the values above referred to near each other, there are no other substances in which the same values come very near or fall within those of the three magnetic substances. The values to which Mr Lyon alludes are the following:[3]

---

[1] Appendix to Captain Back's *Narrative of the Arctic Land Expedition*, &c. p. 601.

[2] *London and Edinburgh Phil. Mag.* December 1834, p. 415.

[3] M. Pouillet, in his *Elémens de Physique*, tom. iii. p. 89, refers to some remarkable analogies which he has observed between the distance of the atoms of bodies and their magnetic properties.

	Specific Gravity.	Atomic Weight.	Atoms contained in a given space.
Nickel	8·27	739·51	1118
Iron	7·21	678·43	1062
Cobalt	7·8	738	1057

The preceding speculation, though ingenious, and deserving of attention, has however been overturned by some very recent observations of M. Faraday. "*Cobalt* and *chromium*," says he, "are said to be both magnetic metals. I cannot find that either of them is so, in its pure state, at any temperatures. When the property was present in specimens supposed to be pure, I have traced it to iron or nickel."[1]

Mr Faraday.

Mr Faraday has very recently published some interesting observations[2] *On the General Magnetic Relations and Characters of the Metals.* He is of opinion that all the metals are magnetic, in the same manner as iron, though not at common temperatures, or under ordinary circumstances. He does not allude to a feeble magnetism, uncertain in its existence and source, but to a distinct and decided power, such as that possessed by iron and nickel; and his impression is, that there is a certain temperature for each metal (well known in the case of iron, beneath which it is magnetic, but above which it loses all power), and that there is some relation between this *point* of temperature and the *intensity* of magnetic force, which the body, when reduced beneath it, can acquire. Iron and nickel would then be no more exceptions from the metals in regard to magnetism, than mercury is in regard to liquefaction.

In order to investigate this point, Mr Faraday subjected various metals in their pure state to a temperature from 60° to 70° below the zero of Fahrenheit, but he could not detect in them the least indication of magnetism. The metals tried were the following:

Arsenic.
Antimony.
Bismuth.
Cadmium.
Cobalt.
Chromium.
Copper.
Gold.
Lead.
Mercury.
Palladium.
Platinum.
Silver.
Tin.
Zinc.
Plumbago.

Mr Faraday next proceeded to compare iron and nickel with respect to the points of temperature at which they ceased to be magnetic. Iron loses all magnetic properties at an orange heat, and is then to a magnet the same as a piece of copper. Mr Faraday found that the point at which nickel lost its magnetic relations was very much lower than with iron, but equally defined and distinct. If heated and then cooled, it remained unmagnetic long after it had fallen below a heat visible in the dark; and almond oil can bear and give that heat which makes nickel indifferent to a magnet, its demagnetising temperature being about 630° or 640° Fahr. In order to determine what relation the temperature which took from a magnet its power over soft iron had to that which would take from soft iron or steel its power relative to a magnet, Mr Faraday gradually raised the temperature of a magnet, and found that it lost its polarity rather suddenly when scarcely at the boiling point of almond oil, and then acted with a magnet as cold soft iron. It required to be raised to a full orange heat before it lost its power as soft iron. "Hence he concludes, the force of the steel to *retain* that condition of its particles which renders it a permanent magnet, gives way to heat at a far lower temperature than that which is necessary to prevent its particles assuming the *same state* by the inductive action of a neighbouring magnet. Hence, at one temperature, its particles can of themselves retain a permanent state; whilst, at a higher temperature, that state, though it can be induced from without, will continue only as long as the inductive action lasts, and at a still higher temperature all capability of assuming this condition is lost. The temperature at which polarity was destroyed appeared to vary with the hardness and condition of the steel. Fragments of loadstone of very high power were then experimented with. These preserved their polarity at higher temperatures than the steel magnet; the heat of boiling oil was not sufficient to injure it. Just below visible ignition in the dark they lost their polarity, but from that to a temperature a little higher, being very dull ignition, they acted as soft iron would do, and then suddenly lost that power also. Thus the loadstone retained its polarity longer than the steel magnet, but lost its capability of becoming a magnet by induction much sooner. When magnetic polarity was given to it with a magnet, it retained this power up to the same degree of temperature as that at which it held its first and natural magnetism."

M. Pouillet.

Some of the results observed by M. Pouillet[3] stand in opposition to some of the preceding statements. M. Pouillet considers it as certain that there are *five* simple magnetic bodies, viz.

Iron,
Manganese,
Nickel,
Chrome, and
Cobalt;

and in consequence of having observed some remarkable analogies between the distance of the atoms of bodies and their magnetic properties, he was led to suppose that the magnetic limit of different bodies ought to be found at very different temperatures. "I have indeed," says he, "demonstrated by experiment, 1. that cobalt never ceases to be magnetic, or rather that its magnetic limit is at a temperature higher than the brightest white heat; 2. that chrome has its magnetic limit a little below the temperature of dark blood-red heat; 3. that nickel has its magnetic limit about 350° centigrade nearly at the melting point of zinc; and, 4. that manganese has its magnetic limit *at the temperature of from 20° to 25° below zero.*[4] Experiments," continues he, "on these five magnetic bodies seem to prove, 1*st*, that heat acts upon magnetism only in consequence of the greater or less distance which it occasions between the atoms of bodies; and, 2*d*, that all bodies would become magnetic if we could by any action whatever make their atoms approach within a suitable distance."

Professor Gauss. A. D. 1833.

Among the latest researches on magnetism are those of Professor Gauss of Göttingen, who has published an account of them in a treatise entitled *Intensitas vis Magneticæ Terrestris ad absolutam mensuram revocatis.* His object is to impart to magnetical observations the accuracy of astronomical ones. By observing the oscillations of a magnetised bar, he finds the product of the horizontal intensity of the earth's magnetism, and the static momentum of the free magnetism of the bar; and by eliminating the latter from the two equations, he obtains an absolute measure of the former, independent of the magnetism of the bar. The horizontal intensity thus found is then to be multiplied by the secant of the dip of the needle, in order to give the absolute intensity. In this inquiry Professor Gauss found it necessary to deduce from observation the true law of magnetic action, which, from a number of consistent and carefully made experiments, he found to be in the inverse ratio of the square of the distance. From a series of accurate experiments,

[2] *Ibid.* p. 177.

[3] *Elémens de Physique*, 2d. edit. tom. iii. p. 89, Paris, 1832.

[4] M. Pouillet remarks elsewhere, that manganese does not become magnetic till it is cooled down to 15° or 20° below zero. (*El. Phys.* iii. p. 18.)

Professor Gauss found the horizontal intensity at Göttingen, on the 18th September 1832, to be 1·7821; and taking the exponent of gravity in moving bodies at the place of observation as the unit of force, and using the Paris line and the Berlin pound, he found the absolute horizontal intensity to be 0·0039131; and as he found the dip at Göttingen on the 23d June 1832 to be 68° 22′ 52″, the absolute intensity of terrestrial magnetism will be

$$\text{Sec. } 68^\circ\ 22'\ 52'' \times 0{\cdot}0039131.$$

Professor Gauss has proposed, and put in practice, a very accurate method of observing the daily variation of the needle, and of determining the time of vibration of a needle or magnetised bar. He fixes a plane mirror on the end of the bar, and perpendicularly to its axis, and by observing the reflected image of the divisions of a scale, by the aid of a theodolite placed at a distance, he is able to observe and to measure the minutest changes.

The magnetised bar employed by Gauss is of much larger dimensions than the bar of Prony's magnetic telescope; the small ones, which he uses as magnetometers, being four pounds weight, and the large ones twenty-five pounds; two of which, when fastened together, form the *apparatus or multiplier* of induction for rendering sensible and measuring the oscillatory movements predicted by a theory founded on Mr Faraday's great discovery. By this valuable invention of Professor Gauss, the observer is not under the necessity of approaching the magnetised bar, so that no disturbance is occasioned by the currents of air produced by the proximity of the observer's body, so that observations may be made in the smallest intervals of time.

With apparatus similar to that of Professor Gauss, simultaneous observations have been made in 1834 and 1836, at intervals of five or ten minutes, at Göttingen, Copenhagen, Altona, Brunswick, Leipsig, Berlin, Milan, and Rome. It appears, from the graphic representation of the results, that the smallest inflexions of the horary curves are parallel, and consequently the disturbing causes which produce them simultaneous at Milan and Copenhagen, two of the places of observation, which have a difference of latitude of 10° 13′.

In giving an account of Professor Hansteen's labours, we have briefly noticed his journey in Siberia, and the erection of magnetic observatories by the emperor of Russia, on the recommendation of Baron Humboldt; and we have also referred to the early researches of this distinguished philosopher. When travelling in the equinoctial regions of America during the years 1799–1804, Baron Humboldt had devoted much attention to the determination of the intensity of the magnetic forces, and of the dip and variation of the needle. Upon his arrival in Europe, he conceived the design of examining the progress of the horary changes of the variation, and the perturbations to which it is subject, by employing a method which had never been adopted on an extended scale. In a large garden at Berlin, he measured, particularly at the period of the equinoxes in 1806 and 1807, the angular alterations of the magnetic meridian, at intervals of an hour, often of half an hour, without interruption, during four, five, or six days, and as many nights. The instrument employed was Prony's magnetic telescope, suspended according to the method of Coulomb, and capable of being reversed upon its axis. It was placed in a glass frame, and directed towards a very distant meridian mark, the illuminated divisions of which indicated six or seven seconds of hourly variation. In these researches Baron Humboldt was struck with the frequency of oscillations whose amplitude extended beyond all the divisions of the scale, and which repeatedly took place at the same hours before sunrise. "These vagaries of the needle," says the baron, "the almost periodical return of which has recently been confirmed by M. Kupffer, in the account of his travels in the Caucasus, appeared to me the effect of a re-action of the interior of the earth towards the surface; I should venture to say, of *magnetic storms*, which indicate a rapid change of tension." With the view of investigating the causes of these disturbances, Baron Humboldt proposed to erect similar apparatus on both sides of the meridian of Berlin; but the political tempest of Germany, and his mission to France by the government, delayed the execution of his plan. M. Arago, however, as we have already seen, began and prosecuted his inquiry with singular success.

General Properties of Magnetic Bodies.

Baron Humboldt.

When Baron Humboldt again fixed his residence in Germany in 1827, he erected one of Gambey's compasses in a magnetic pavilion, without any iron, in the middle of a garden, and began a series of regular observations in the autumn of 1828. At his request, the Imperial Academy and the curator of the university of Kasan erected magnetic observatories at St Petersburg and Kasan; and the imperial department for mines has established similar stations at Moscow, Barnaoul, and Nertschinsk. The academy, too, has sent Mr George Fuss to Pekin, where he has procured the erection of a magnetic pavilion in the convent garden of the monks of the Greek church. Since Mr G. Fuss's return, M. Kowanko, a young officer of mines, continues the horary observations corresponding to those made in Germany and Russia. Admiral Greig has established one of Gambey's compasses in the Crimea at Nicolaeff. Baron Humboldt has procured the establishment of a magnetic apparatus at the depth of thirty-five fathoms, in an adit in the mines of Freiberg in Saxony. Baron Von Wrangel has been provided with one of Gambey's compasses at Sitka, in one of the Russian settlements. M. Arago has caused to be erected, at his own expense, one of Gambey's compasses in the interior of Mexico, where the soil is 6000 feet above the sea. The French minister of marine has established a magnetic station in Iceland, and the necessary instruments will be sent this summer (1836) to Reikavig; and Baron Humboldt, at the desire of Admiral de Laborde, has sent instruments to the Havannah in Cuba, to furnish a magnetic observatory under the tropic of Cancer.

Some years ago, the writer of this article urged a distinguished and influential member of the British government to establish magnetic observatories in England and the colonies, but no steps were taken in consequence of this application. Baron Humboldt has, however, addressed an interesting letter to his Royal Highness the Duke of Sussex, as president of the Royal Society, soliciting this body to extend, in the colonies of Great Britain, the line of simultaneous observations, and to establish permanent magnetic stations, either in the tropical regions on each side of the magnetic equator, or in the high latitudes of the southern hemisphere, and in Canada. We hope that the Royal Society will use its influence with the British government to have this proposal carried into effect, and that this country shall not be exposed to the humiliation of being indifferent to the progress of those branches of scientific inquiry which its extensive influence in various regions of the globe enables it effectually to advance.

CHAP. II.—ON THE GENERAL PHENOMENA AND PROPERTIES OF MAGNETIC BODIES.

General properties of magnetic bodies.

A body is said to be magnetic when it has the power of attracting soft iron, either in the subdivided state of iron filings, or in large portions; or of attracting and repelling other magnetic bodies like itself: of taking a particular position when freely suspended, or moving on a pivot: and of communicating magnetism either temporarily to soft or permanently to hard iron in the form of steel. Hence we may arrange the general properties of magnetic bodies under the following heads.

General Properties of Magnetic Bodies.

1. On the attractive power of magnetic bodies upon soft iron.

2. On the attractive and repulsive power of magnets over each other, or over iron either temporarily or permanently magnetised.

3. On the effect of masses of iron on the attractive force of a magnet.

4. On the polarity of magnetic bodies.

5. On the power of magnets to communicate magnetism to other bodies.

6. On the distribution of magnetism in artificial magnets.

7. On the effect of division and fracture on the distribution of magnetism.

8. On magnetic figures.

SECT. I.—*On the Attractive Power of Magnetic Bodies upon Soft Iron.*

Attraction of magnets over iron.

The natural magnet or loadstone was for a long time the only body considered as possessing magnetic properties. It is an ore of iron, of a grey colour, and a dark metallic lustre. Its specific gravity is about four and a half times that of water. It crystallizes in the form of the regular octahedron, and it consists of from 85 to 75 parts of iron, and from 15 to 25 parts of oxygen. It is found in almost every part of the world,[1] and often forms rocks of considerable magnitude; but different specimens of it possess very different powers of attraction.

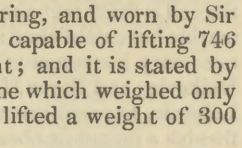
Loadstone.

The smallest loadstones generally have a greater attractive power in proportion to their size than larger ones. They have been found of such strength, that though weighing only about twenty-five grains, they could lift a piece of iron about forty-five times heavier than themselves. A small magnet set in a ring, and worn by Sir Isaac Newton, is said to have been capable of lifting 746 grains, or 250 times its own weight; and it is stated by Cavallo, that he has seen a loadstone which weighed only about six and a half grains, which lifted a weight of 300 grains.

Natural loadstones often possess unequal powers of attraction in different parts of their mass, in consequence of want of homogeneity of structure and composition; and hence a portion has often been cut from a large loadstone which could lift a greater weight of iron than the large one itself, the portion detached having possessed the most suitable structure, and the other part having weakened the action of the powerful part by keeping the body to be lifted at a greater distance from those points where the magnetism was strongest. It is no doubt from a similar cause that small magnets have a greater proportional power than large ones, or that those of two pounds weight have seldom been found capable of lifting more than *ten* times their own weight of iron.

If we now take a natural loadstone L, however shapeless, and, after rolling it in a quantity of iron filings, afterwards withdraw it, we shall find that the filings are accumulated more abundantly in two opposite points A, B, than in any other, as shown in fig. 1. These two points A, B are called the poles of the magnet, and are the points of greatest attraction. When either of these poles is held at a distance from the iron filings, the filings will be attracted to it, and will adhere with such force that it is difficult to brush them off.

Fig. 1.



If we suspend a small needle of iron or steel by a fine linen or silken fibre, or balance it on a pivot, and bring the poles of the loadstone L near it, it will be attracted to it in the first case, or will oscillate on its pivot in the second case.

If we make the needle float on water in a glass tumbler, and bring any pole of L on the outside of the tumbler, the needle will be attracted towards the pole, notwithstanding the interposition of the glass; and by using the needle upon a pivot, it will be found that the attractive force of the loadstone is in no respect diminished by the interposition of any substance whatever, except iron, conductors and non-conductors of electricity having no effect whatever in stopping or diminishing the action of the loadstone, unless the interposed body be iron, or contains iron in any of its metallic states.

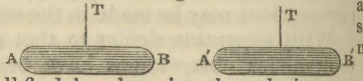
While the loadstone thus attracts iron, and all bodies containing it in a metallic state, these same bodies exercise a reciprocal attraction upon the loadstone, action and re-action being equal and opposite. The truth of this may be exhibited by suspending a magnet, and bringing into the vicinity of its poles a piece of soft iron. The magnet will be gradually attracted by the iron, in the same manner as if the iron had been suspended and a pole of the magnet held near it.

SECT. II.—*On the Attractive and Repulsive Power of Magnets over each other, or over Iron either temporarily or permanently magnetised.*

Attraction and repulsion of magnets.

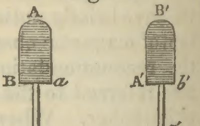
If we suspend near each other two loadstones, AB, A′B′, like that shown in fig. 1, by two threads T, T, we shall find, by changing the relative position of their poles, A B, A′ B′, that there are certain positions in which these poles attract each other, and others in which they are repelled. By marking the poles which attract each other, such as A, B′ and A′, B, we shall find that the poles which repel each other are A, A′ and B, B′, and that this mutual attraction and repulsion takes place under every change of circumstances.

Fig. 2.



If we suspend a piece of soft iron *ab* from a loadstone AB, we shall find that the end *b* of the iron exercises the same attractive and repulsive power upon the poles A′ B′ (fig. 2) of a suspended magnet that B did; and in like manner, if the piece of iron *a′b′* is suspended from the pole A′, the end *a′* will exercise the same attraction and repulsion upon the poles of a suspended magnet that A did.

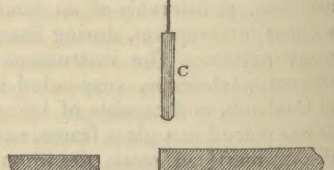
Fig. 3.



SECT. III.—*On the effect of Masses of Iron on the Attractive Force of a Magnet.*

Effect of masses of iron on the attractive force.

Fig. 4.



If we suspend a piece of iron C from the arm of a balance, it will be attracted by the pole P of a magnet A, and will descend towards P in virtue of this attraction. If we now place a mass of iron I close to A, the suspended iron C will rise, as if the attractive force of P were diminished. This power of the mass of iron I seems only to extend to a given point within the magnet A, the distance between the magnet and the iron remaining the same;

---

[1] According to Norman, the best loadstones were those brought from China and Bengal.

for if the iron C is suspended above a point x at some distance from P, the action of I will not be felt at the point x, except by diminishing the distance between P and C, or by increasing the neutralising power of the mass I.

Mr Snow Harris, to whom we owe this experiment, has shown that a similar effect is produced when the iron I is placed between the magnet PA and the suspended iron C, and also when I is placed below P. In the first of these cases I stops the attraction of P upon C, and acts as a screen.

SECT. IV.—*On the Polarity of Magnetic Bodies.*

If we suspend a loadstone, as in fig. 2, or make it float upon water or mercury, by placing it on a thin plate of cork or wood, it will gradually change its place till it rests in a position where a line joining the poles A, B is nearly north and south. This is, generally speaking, the case in Europe, the end A, which points northward, deviating in some places from the meridian to the west, in some places to the east; while in other parts of the globe it points exactly to the north. The deviation of the loadstone from the meridian is called its *declination* or *variation*. This property of the magnet is called its *polarity*, or *directive power;* and the pole A, which turns to the north, is called its *north pole;* and the pole B, which turns to the south, its *south pole*. It will now be found that the poles and magnets A, A′, or B, B′, which repel each other, are either both *north* or both *south* poles; and that the north and south poles attract each other. Hence there is in magnetism, as there is in electricity, two opposite powers or principles, namely, the *northern* and the *southern*, or boreal and austral magnetism; and, as in electricity, a *repulsion* takes place between the two powers of the *same* name, and *attraction* between the two powers of an *opposite* name.

The magnetism from which loadstones derive their polarity, or their tendency to direct themselves to particular points of the compass, is obviously derived in some way or other from the earth or its atmosphere; and hence it is called the *Magnetism of the Earth*, or *Terrestrial Magnetism*, which will be treated more fully in a future part of this article.

SECT. V.—*On the Power of Magnets to communicate Magnetism to other Bodies.*

We have already seen, that if a piece of soft iron is suspended to a magnet by the attraction of one of its poles, the iron becomes magnetic, but only during the time that it is in contact with the loadstone. But if we use a piece of hardened iron, or steel, $a\ b$, and suspend it as in fig. 3, it will be found to have acquired a permanent magnetism, the strength of which will depend on the power of the natural magnet A B, and on the time which the steel bar has been suspended. The pole a will be a *north* pole similar to A, and the pole b a *south* pole similar to B; and the little magnet $a\ b$ will possess all the properties of the natural magnet, such as attraction for soft iron, and polarity; and its action upon another little steel magnet $a'\ b'$, made in a similar manner, will be the same as the action of two natural magnets upon each other. A steel magnet thus made is called an *artificial magnet;* and we shall in the sequel consider the magnets of which we speak as steel bars rendered permanently magnetic.

A little magnet $a\ b$ has been made by a very simple process, namely, that of contact with the pole of a natural magnet; but there are more complex and efficacious methods, by which a very high degree of permanent magnetism can be communicated to steel, which will be fully explained in the practical part of this treatise.

In order to communicate magnetism from a natural or artificial magnet to unmagnetised iron or steel, it is not necessary that the two bodies be in contact. The communication is effected as perfectly, though more feebly, when the bodies are separated by space.

Magnetic induction.

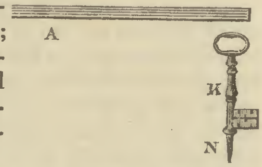
Fig. 5.

If the *north* pole N of an artificial steel magnet A is placed near the extremity s of a piece of soft iron B, the end s will instantly acquire the properties of a *south* pole, and the opposite end n those of a *north* pole. The opposite poles would have been produced at n and s if the south pole S of the magnet A had been placed near the iron B.

In like manner, the iron B, though only temporarily magnetic, will render another piece of iron C, and this again another piece D, temporarily magnetic, north and south poles being produced at n', s', and n'' s''.

The magnetism inherent in B, C, and D, is said to be *induced* by the presence of the real magnet A, and the phenomena are exactly analogous to the communication of electricity to unelectrified bodies by induction, the positive state inducing the negative, and the negative the positive, in the parts of a conductor placed in a state of insulation near an electrified body.

Fig. 6.



In order to show by simple experiments that soft iron is itself a magnet while placed near a magnet, let A be a magnet, and K a key held near its lower edge. A nail N will remain suspended by virtue of its induced magnetism; but if A is withdrawn, or K removed from A, the nail N will instantly fall, the induced magnetism diminishing with the distance.

If we hold the key K above a portion of iron filings, they will not be attracted by it; but if we then bring the magnet A near the ring of the key, as in the figure, the iron filings will instantly start up, and be attracted by the key.

Re-action of iron on magnets.

We have already noticed, in Sect. I., that the iron attracted by a magnet re-acts upon the magnet, and attracts it in return. The same is the case with a bar of iron on which magnetism is induced. It re-acts on the magnet which induces its magnetism, and increases its magnetic intensity. Hence we derive a distinct explanation of the remarkable facts, that a magnet has its power increased by having a bar of iron placed in contact with one of its poles, and that we can gradually add more weight to that which is carried by a magnet, provided we make the addition slowly and in small quantities, the power of the magnet being increased by the re-action of each separate piece of iron that it is made to carry.

Consecutive poles.

If the bar of iron on which magnetism is induced is long, and the strength of the magnet great, a succession of poles is produced along its length, a north pole always following a south pole, and *vice versa*.

Magnetic attraction and repulsion explained.

These facts enable us to explain the phenomena of magnetic attraction and repulsion, which are necessary consequences of magnetic induction. The magnet attracts a piece of iron by inducing an opposite polarity at the end in contact with it, and the two opposite principles attract each other. In like manner, the north pole of one magnet attracts the south pole of another, and the north and south poles repel each other, in consequence of the attraction and repulsion of the opposite or similar principles. The attraction of iron filings is explained in the same manner. The particle of iron next the magnet has magnetism induced upon it, and it becomes a minute magnet, like B in fig. 5. This particle again makes the next particle a magnet, like C, and so on, the opposite polarities in each particle of the filings attracting one another, as if they were real magnets.

In comparing the amount of the *attractive* force of two *dissimilar* poles of two magnets, with the amount of the *repulsive* force of the two similar poles, it has been found that the former force is considerably greater than the latter. This result is a necessary consequence of the inductive process above described. When the two attracting poles are in contact, each magnet tends to increase the power of the other, by developing the opposite magnetisms in the adjacent halves, and thus increasing their mutual attraction. But when the two repelling poles are brought into contact, the action of each half brought into contact has a tendency to develope in that half a magnetism opposite to that which it really possesses, and thus to diminish the two similar principles, and weaken their repulsive power. This injurious influence of opposite poles upon the repulsive power of the magnets in action, is finely exhibited when one of the magnets is very powerful, and the other very weak. When the two similar poles are held at a moderate distance, a repulsion is distinctly exhibited; but when they are brought into contact, the stronger *attracts* the weaker magnet, an effect which is produced by its actually destroying the similar weak magnetism in the half next it, and inducing in that half the opposite magnetism, which, of course, occasions attraction.

When the magnet A and the piece of iron B are placed in the same straight line, as in fig. 5, the pole N acts favourably in inducing south polar magnetism at *n*, and north polar at *s*; but it is evident that the remote pole S must tend to weaken the inductive force of N, by inducing, though in a feeble degree, north polar magnetism at *n* and south polar at *s*. If the soft iron B is placed as in fig. 7, the induced magnetism will be nearly as strong as before, the greater proximity of N tending to produce south polar magnetism in *n*, being compensated by the increased proximity of S tending to produce north polar magnetism in *n*. In the inclined position C the induced magnetism is still stronger, as S acts more powerfully upon *n*; and when the two are parallel, as in fig. 8, the two bars or magnets are in the position most favourable for developing and sustaining the magnetism which they receive or possess.

Fig. 7.

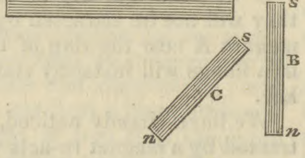


Fig. 8.

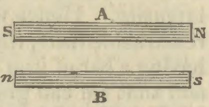

Hitherto we have considered the natural and artificial magnet as producing magnetism in soft or hard iron, distributed in the same manner as in the inducing magnet; but by the action of one or more magnets, we can distribute the magnetism in various ways, as follows:

In the case of bars, we may have a north pole in the middle of it, and a south pole at each extremity. Thus, in fig. 9, if the magnet NS has its north pole N placed opposite the middle of the soft iron bar *nn*, this bar will have a south pole at *s* and north poles at *n*, *n*. The very same effect will be produced if, as in fig. 10, we place the soft iron bar B between two magnets A, C, whose north poles N, N are nearest the bar. These north poles N, N tend to produce south poles at *s*, *s*, and consequently northern polarity in the middle at *n*. In the preceding case a south pole may be produced in the middle, and north poles at the ends of the bar, by placing the south poles of the magnets where the north poles are placed.

Fig. 9.

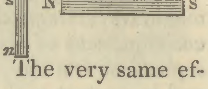

Fig. 10.

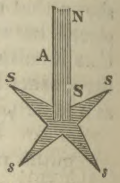
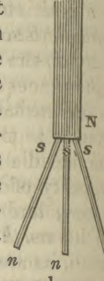
In like manner, a piece of soft iron *s s*, *s s*, of the form of a cross, will have south poles at *s*, *s*, *s*, *s*, if the south pole S of a magnet A is placed on or near its centre, as in fig. 11, as it may be conceived to consist of two bars *s s*, *s s*. For the same reason, if a circular plate of soft iron is substituted in place of the cross *ss*, *ss*, and the south pole S of the magnet placed upon or near its centre, that centre will be a north pole, and every point of the circumference of the plate will be a south pole.

Fig. 11.



A very instructive experiment, founded on magnetic induction, is exhibited in fig. 12, where several soft iron wires or slender bars *sn*, *sn*, *sn* are suspended at the north pole N of a magnet N. Each of the ends *s*, *s*, *s* becomes a south pole by induction from the action of the north, and consequently the lower ends *n*, *n*, *n* north poles. The south poles *s*, *s*, *s* have a tendency to repel each other, but are prevented from yielding to their repulsive forces in consequence of their strong adhesion to the north pole N. The north poles *n*, *n*, *n*, however, are free from this restraint, and exhibit their mutual repulsion by their diverging, as shown in the figure. Hence we see the reason why rows of iron filings adhering to each other, when attracted by a magnet, keep separate from each other by the repulsive forces of the similar poles.

Fig. 12.



In the following form of the experiment given by Cavallo, the repulsion of both poles is well illustrated. If we suspend two short pieces of soft iron wire *ns*, *ns* by threads, they will hang in contact in a vertical position. If we now bring the north pole N of a magnet A to a moderate distance from the wires, they will recede from each other, as in fig. 13. The ends *s*, *s*, being made south poles by induction from the north pole N, will repel each other, and so will the north poles *n*, *n*. This separation of the wires will increase as the magnet A approaches nearer them; but there will be a particular distance at which the attractive force of N overcomes the repulsive force of the poles *s*, *s*, and causes the wires to converge, as in fig. 14, the north poles *n*, *n* still exhibiting their mutual repulsion.

Fig. 13.

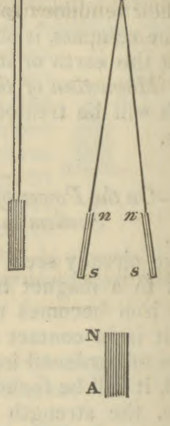


Fig. 14.

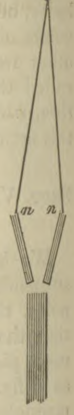
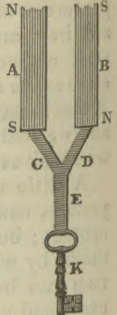


The neutralisation or destruction of induced magnetism, by two equal and opposite magnetic actions, is shown in the following experiment, given by Dr Robison. If we take a forked piece of soft iron CDE, and suspend it by the branch D from the north pole of a magnet B, it will be magnetised by induction, and will carry a key at its lower end E, which will be a north pole. If we now apply to the other branch C the south pole S of another and equal magnet A, the key will instantly drop off. This obviously arises from the south pole S inducing a south pole at E, which either destroys or neutralizes the north polar magnetism previously induced by N.

Fig. 15.



SECT. VI.—*On the Distribution of Magnetism in Artificial Magnets.*

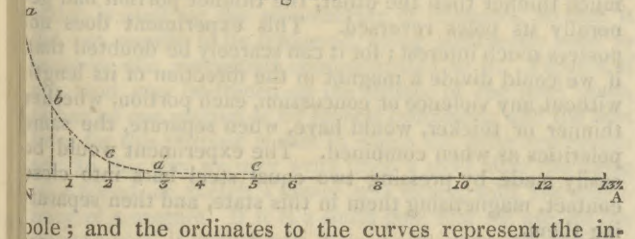
It is very obvious, from the preceding experiments, that in regular magnets, with a north pole at one end and a south pole at the other, the two kinds of magnetism, north polar and south polar, are equally and regularly distributed, the one occupying one half of the magnet, and the other the other half. It is obvious also that each kind of magnetism has no intensity at the centre of the magnet, or its middle part, and that it increases, according to some regular law, from that point towards the two poles at the extremities of the magnet.

The first person who determined the law of distribution which we have now mentioned was M. Coulomb. The magnet which he employed for this purpose was a cylinder two lines in diameter, twenty-seven inches long, and its weight 1946 grains; and he ascertained the intensity of magnetism at each point, from its middle to its extremity, by observing the number of oscillations which a small magnetic needle performed in a minute, when it was made to oscillate before different points of the wire. He had previously observed the number of oscillations which the same needle performed out of the sphere of the magnet, and he considered the magnetic intensity as proportional to the difference of the squares of those two numbers of oscillations. The first needle which he employed was three lines in diameter and six lines long, and it was made of such a size, and of such hardness, that its magnetism should not be perceptibly altered by the action of the wire during the experiments; for if any change did take place, the results obtained at different points of the magnet could not be compared. The great length of twenty-seven inches was given to the magnet, in order that its remoter pole might be so distant from the needle that it would be unnecessary to make any allowance for its action upon the oscillations of the needle. In this way Coulomb obtained the following results:—

Distances from the North Pole of the Magnet.	Observed Intensity of the Magnetism at these distances.
0	165
1	90
2	48
3	23
4, 5	9
6	6

The distribution of the magnetism is exhibited in fig. 16, where AN is half of the magnet, and N its north pole; and the ordinates to the curves represent the intensities in the preceding table.

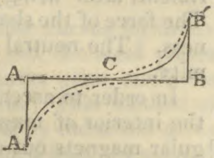
Fig. 16.



These experiments were repeated by Coulomb, with magnets of the same shape and diameter, but of a less length, all other circumstances being unchanged, and he obtained nearly the same results for the three inches of the magnet nearest N; and hence he concluded, that whatever was the length of the magnet, provided it was greater than six or seven inches, the three inches at both its north and south poles gave always the same results as the twenty-seven inch magnet. From this point towards the centre the magnetism became weak and insensible in all of them; and in very long magnets he even found that the ordinates sometimes passed from positive to negative.

M. Biot has remarked that the curve of intensity, as determined by Coulomb, results from the combination of two logarithmic curves ACB′, A′CB, which, setting out from each pole A, B of the magnet AB, would have their ordinates equal and in an opposite direction, as shown in fig. 17. The intensities calculated upon this supposition agree exactly with the observed results.

Fig. 17.



Becquerel's experiments.

As Coulomb had examined the distribution of magnetism only in magnets of considerable size, M. Becquerel[1] was desirous of ascertaining if the law was observed in steel wires of a small diameter, such as $\frac{1}{80}$th of a millimetre, or $\frac{1}{2000}$th of an inch. In order to procure such wires, he encased a steel wire one millimetre in diameter in a cylinder of silver, and having drawn out the whole into a wire, the silver was removed by means of boiling mercury. He employed the method used by Coulomb in determining the law of distribution; but, on account of the fineness of the wires, and the weakness of the magnetism which they acquired, he was obliged to make some changes in the method. He obtained, however, the very same results as those given by Coulomb.

Kupffer's experiments.

A number of interesting experiments on the distribution of magnetism have been made by M. Kupffer of Kasan,[2] by means of the method of Coulomb. He employed a flat and very narrow needle, twelve millimetres long, and he placed it at a horizontal distance of three decimetres from a cylindrical bar magnet of cast steel not tempered, 607 millimetres long and 12½ millimetres thick. He began his experiments with magnets that possess a weak degree of magnetism. In magnetising them, he rubbed the steel bar perpendicularly on the *north* pole of a very strong artificial magnet, and he replaced the bar vertically before the needle, the north pole of the former being uppermost. He found that the south pole was stronger than the north pole, and that the point of indifference, or the neutral point, was nearer the stronger pole than the other. Upon reversing the magnet, the magnetic intensities of its different points increased, and the neutral point approached the middle of the magnet. These changes were produced successively, and the magnet did not attain its final state till it had remained some time in the same position. Kupffer observed, that whenever the magnetic intensities of the bar increased, the neutral point slowly approached the middle point; that this point was always nearer the stronger pole; that a bar magnetised vertically was always more powerful when its north pole was downwards; and that a bar magnetised by the method mentioned above was always strongest in the pole immediately produced by that of the magnet.

After detailing his observations with a bar magnetised to saturation, he proceeds to determine the influence exercised by the form of the extremities of the bar on the magnetic intensity, and on the position of the neutral point. A cylindrical bar of steel, cast but not tempered, having been rounded at one of its ends, and magnetised to saturation, was placed fourteen centimetres from a magnetic needle, and in the line of its direction. When its north pole was directed to the south, the force of the rounded north pole was 2·0319, and that of the south pole was 2·1558. In the opposite position of the bar, the magnetic force of the north pole was 2·2198, and that of the south pole 2·3006, the neutral point being in the middle.

---

[2] *Ibid.* tom. xxvi. p. 50.

The rounded end of the bar was now filed to a point, and made sharper and sharper in every successive experiment, after being each time magnetised to saturation. The force of the sharpened pole diminished with its acuteness. The neutral point receded always from this extremity.

Distribution of magnetism in the interior of magnets. Coulomb's experiments.

In order to ascertain the distribution of magnetism in the interior of magnets, Coulomb formed sixteen rectangular magnets out of the same piece of steel. Each was six inches long, nine and a half lines wide, and 382 grains in weight. They were annealed at a white heat, without being tempered, in order that he might be certain of having them always in the same state. He magnetised them all to saturation, and formed bundles with a certain number of them, similar poles being placed together. The magnets in each bundle were bound tightly together with a strong silk thread. Each bundle was then placed in a torsion balance, and placed 30° out of the magnetic meridian. The force of torsion necessary to retain it in this position was a measure of its magnetic intensity. The following were the forces or degrees of torsion necessary to keep the different bundles at rest.

	Degrees of Torsion.
1 magnet	82°
2 magnets united	125
4 magnets united	150
6 magnets united	172
8 magnets united	182
12 magnets united	205
16 magnets united	229

Hence it follows that the magnetic force of each bundle increases in a ratio much less than that of the number of plates.

Coulomb next determined the magnetic state of each of the magnets composing the bundles of eight and sixteen magnets; and he found that the two outermost magnets, those which formed the surface of the bundles, had a much greater force than the rest.

The first had a force which measured	46
The second	48
And the mean force of all the rest was	30

A single magnet had its directing force 82°, while for sixteen of them united the mean directing force of each was only 14°·3, that is, about the sixth part of the other.

In examining the bundle of eight magnets by the method of oscillation, he found that the two outermost performed twenty oscillations in $90\frac{1}{2}$ minutes, while all the rest performed the same number in from 211 to 278 nearly, showing the weakness of their magnetism. It is curious that the outermost but one had its poles reversed.

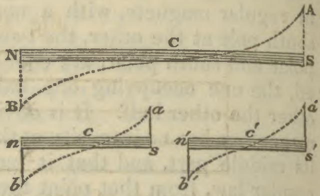
Coulomb also found that a bundle of magnets will take nearly the same degree of magnetism as a single magnet of the same shape and weight; which leads us to believe that, in magnets of one piece, the magnetism diminishes from the surface to the centre, as in the preceding bundles of magnets.

SECT. VII.—*On the Effect of Division and Fracture in the Distribution of Magnetism.*

Effects produced by breaking magnets.

As no natural or artificial magnet has ever been seen with only one pole, or one kind of magnetism, it became interesting to determine experimentally the distribution of magnetism in a part of a magnet cut from its north or south extremity. This experiment has been often made, both by cutting it through at the middle or neutral point, or by cutting or breaking off a portion from the end of it. If NS, for example, is a magnet, N its north and S its south pole, and ACB the curve representing the intensity of its magnetism; then, if we cut it through the middle C, each half *ns*, *n's'* will be a complete magnet, with a north pole at *n*, and a south one at *s*, and their neutral points at *c*, *c'*; the curves at *acb*, *a'c'b'*, representing the distribution of their north and south polar magnetism, being similar to the curve ACB of the large magnet of which they are the halves.

Fig. 18.



When Æpinus made this curious experiment, he did not divide the magnet in two, but he set two steel bars end to end, and magnetised them as one magnet, so that this compound magnet had its magnetism distributed as in a single bar, like NS, fig. 18. He then separated them, and found that each bar was a perfect magnet, with two poles. Dr Robison repeated this experiment successfully on some occasions; but he sometimes found indications of the compound magnet acting as two magnets. We are persuaded that this arose from an imperfect union of the two bars, and not from any defect in Æpinus's experiment. The united ends of the bars should be ground together, so as to be kept in perfect contact, and preserved in this state by a powerful pressure during the time that they are magnetised. If this be done, we have no doubt that they will act on iron filings, and throw them into curves, as if they were a single bar, and will, by examination with a fine needle, exhibit the same regular distribution of magnetism which takes place in the most perfect magnet.

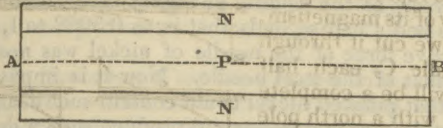
Upon the separation of the magnets thus united, Æpinus found that two poles were instantly developed in each half, but that the neutral points *c*, *c'*, fig. 18, were nearer the interior poles *s*, *n'*, or, what is the same thing, nearer the original neutral point C, than to *n* and *s'*. In the space of about a quarter of an hour it had, however, advanced nearer to the middle points *c*, *c'*, and continued for some hours, and sometimes for days, to advance to these points, which it finally reached, thus completing the regular distribution of the two opposite magnetisms.

Some observations, but not very accurate ones, have been made on the division of magnets in the direction of their lengths. According to Dr Derham, the two portions sometimes have contrary, and sometimes the same poles, as when they were united. When one portion was much thinner than the other, the thinner portion had generally its poles reversed. This experiment does not possess much interest; for it can scarcely be doubted that, if we could divide a magnet in the direction of its length without any violence or concussion, each portion, whether thinner or thicker, would have, when separate, the same polarities as when combined. The experiment would be easily made by pressing two equal steel bars into close contact, magnetising them in this state, and then separating them.

Analogy between magnets and unannealed glass.

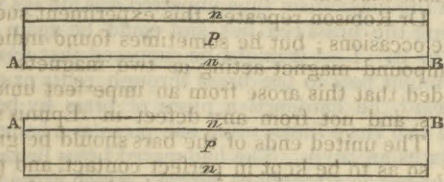
A very remarkable analogy has been pointed out by Sir David Brewster, between the preceding results and those which he has obtained with parallelopipeds of glass which received the doubly refracting structure by being quickly cooled on all their surfaces from a state of red heat. This change is analogous to that of temper in a magnet; and the effect of it is to produce a certain development of positive and negative double refraction throughout the whole of the parallelopiped of glass. These phenomena will be minutely explained in our article on OPTICS; but we may state at present, that the structure of the glass modifies the action of the ether which it contains, just as the structure of the tempered steel keeps the two magnetisms in an uncombined state. This is shown in fig. 19, where

Fig. 19.



AB is a thick plate of glass quickly cooled. The middle portion of it P has positive, and the external portions N, N, negative double refraction. The density of the ether in each of these portions varies according to a regular law; and the intensity of the doubly refracting force, at different points both of the positive and negative structures, is represented by a curve formed by the superposition of a straight line and a parabola. If we now cut the parallelopiped of glass into two halves, through the dotted line AB, fig. 19, each half will have the same structure as the whole, as shown in fig. 20; the parts that were formerly *positive* being now *negative*, and *vice versa;* and the intensity of the doubly refracting force in each half will be represented by the ordinates of a curve formed by the superposition of a straight line and a parabola. This fact is in perfect analogy with the magnetic one, and there are many other remarkable points of resemblance which we have not space to describe at present.

Fig. 20.



SECT. VIII.—*On Magnetic Figures.*

Magnetic figures.

In our article on ELECTRICITY we have given an account of the beautiful electrical figures discovered by M. Lichtenberg, and which form one of the most interesting popular experiments in that science. We are indebted to M. Haldat of Nancy for the analogous discovery of magnetic figures, which may be easily produced. For this purpose he employs plates of steel from eight to twelve inches square, and from one twentieth to one eighth of an inch thick. The plates which he used were of that kind of steel which is used for the manufacture of cuirasses, so that it did not require to be tempered, being sufficiently hard to preserve the magnetism communicated to it. Figures of any kind may be traced on the surface of the steel plate, either by one magnet or by several combined; and the best form for this purpose is that in which the poles are rounded. In this way we may write upon a steel plate the name of a friend, or sketch a flower or a figure, with the extremity of a magnet. If it is a south pole that we use, all the traces which it makes will have north polar magnetism; and if we shake steel filings upon the plate out of a gauze bag, the filings will arrange themselves in the empty spaces between the lines traced by the pole of the magnet, and thus represent in vacant steel the name which has been written, or the flower or figure which has been sketched. "These figures," says M. Haldat, "have a perfect resemblance to those which are formed on the surface of non-magnetic plates, viz. wood, card, glass, or paper, under which a magnet is placed. The resemblance between the two sorts of figures, when the magnets and the parts magnetised have the same form, is not only exact in the whole figure, but even in the smallest details. The filings collect at the parts where the magnetism is most intense, they arrange themselves in pencils and radii, and form the same curves which we have represented in fig. 1, page 702. These curves, and pencils, and rays, so similar at the two poles of the same magnet, have such a resemblance that they do not allow us to distinguish the two parts from one another."

General Properties of Magnetic Bodies.

Magnetic figures.

M. Haldat has likewise produced these curves by interposing between the tracing magnets and the steel plates solid non-magnetic bodies, such as cards, glass, and even metallic plates that are not ferruginous. This method of producing magnetism in the steel plate by induction gives the same figures; but, in order to be efficacious, the magnet must have its pole carried parallel to and at a small distance from the plate of steel, and must repeat its traces, in order that the magnetism may be sufficiently developed. For rectilineal figures, M. Haldat employs rules with grooves, which keep the motion and distance of the bar invariable; for curvilineal figures he interposes some thin and uniform plate, and he can vary the distinctness of the figures by varying the distance of the tracing pole of the magnet.

In sifting the iron filings upon the steel plate, a gentle vibration of the plate, by tapping its edge with the ring of a small key, will assist the filings in taking their proper places; but we must avoid such vibrations as will produce regular acoustic figures, unless we wish, as M. Haldat has found to be practicable, to unite the magnetic with the acoustic figures, which produces very interesting and varied forms.

M. Haldat has found that the magnetic figures will continue for six months. In order to remove the magnetism which produces them, he recommends the heating of the plate upon red-hot charcoal, till it is brought to the straw-yellow temperature. In order to render the repolishing of the plate unnecessary, M. Haldat tins it, and the temperature at which the tin melts, when it is required to efface the magnetism, indicates the necessary heat. M. Haldat employs also another method, which is perhaps the best. He places the steel plate upon a block of wood, and by repeated and violent blows of a wooden hammer he removes the magnetism of the plate, the figures gradually becoming weaker and weaker when the experiment is tried with it in different stages. The effect is often produced in three or four minutes.

As the figures traced on the steel are nothing more than magnets of different forms, and are surrounded on all sides with a substance capable of acquiring the magnetism which may be developed by communication, we might expect, as M. Haldat remarks, that this means of communication between the opposite poles of the magnets would bring them into a neutral state. This, however, is not the case, and the portion of the metal which surrounds the magnetic figure performs the part of the *armature* of a loadstone, and the magnetism is thus kept up. If the figure be a simple rectangle, like that of a bar-magnet, the state of the plate, examined with a small needle, is exactly the same as a bar-magnet, and the parts which surround this magnetic portion are in a neutral state, as if unconnected with the rectangular space; from which it follows that the magnetic virtue, which communicates itself so easily by influence, ceases to communicate itself between the continuous parts of a magnetisable body, of which one portion is magnetic, and the rest in a neutral state.

Improvements on M. Haldat's method.

In carrying into effect the preceding method of making magnetic figures, a very great difficulty must be experienced in recollecting the invisible traces made by the pole of the magnet, so as to complete a regular figure or drawing. When the figures are made *immediately*, as M. Haldat ex-

Magnetic figures.

presses it, that is, by the actual contact of the pole of the magnet, without any intermediate body, the best method would be to cover the plate of steel with the slightest coating of grease, and sift upon the surface, through a linen bag, some of the finest flour. The pole of the magnet, while tracing the figures on the steel, will remove the flour, and thus exhibit to the eye an accurate picture of what it has traced; and it will thus be easy to make the magnetic figures more distinct by repeating the traces with the magnet. The same thing may be done by putting an etching ground upon the steel plate, and tracing the figure as before. When the figure is completed, the coating of grease and flour, or the etching ground, must be removed previous to the application of the iron filings.

When the figures are to be produced *mediately*, or by the intervention of a non-magnetic substance, such as paper, card, wood, or glass, a fine dust may in like manner be laid upon the surface; but when the interposed substance will receive the mark of a pencil or sharp point, it would be preferable to attach to the cylindrical pole of the tracing magnet a very short point of a non-magnetic substance, which would make a visible mark on the paper, card, or wood, without strewing any fine dust on their surfaces. By the use of such a point, indeed, we may dispense altogether with the interposed substance, and communicate the magnetism by induction to the steel plate, in the very same way as if it had been done by the intervention of a non-magnetic plate whose thickness is equal to the length of the short point or tracer affixed to the pole of the magnet.

The magnetic figures might be rendered permanent by covering the steel plate either with a gummy or balsamic solution, which will indurate by exposure to the air; or with a coating of some easily melted substance, which becomes fixed at ordinary temperatures. If we sift the iron filings on the steel plate when covered with such a fluid, the filings will take their magnetic position round the traced lines, and will become fixed by the induration or solidification of the fluid coating.

CHAP. III.—ON THE MAGNETISM OF BODIES NOT FERRUGINOUS.

SECT. I.—*On the Magnetism of Metals, Minerals, and other Bodies.*

Magnetism of metals, &c. not ferruginous.

Iron was long regarded as the only body endowed with the property of acting and of being acted upon as a magnet; and though other metals and substances have been recently found to possess the same property, and though all substances whatever have been found by Coulomb to obey the power of a strong magnet, yet it is still a matter of doubt whether the magnetic effects thus produced are owing to a magnetism residing in the proper substance of the body, or are owing to a minute quantity of iron which enters into their composition.

Magnetism of nickel.

The most magnetic metal next to iron is *nickel*. It receives and retains communicated magnetism longer than any other metal, and needles of nickel have a distinct polarity. These properties have been found in nickel after it has been repeatedly purified, though some authors have stated that they could not detect this property in certain specimens. A very decisive and instructive experiment on the magnetic qualities of nickel was made by M. Biot.[1] He possessed a needle of nickel which had been purified by M. Thénard. It was 212 millimetres long, six broad, and 5·178 grains in weight. Having made a needle of steel of exactly the same dimensions, and which weighed 4·586 grains, he magnetised them both to saturation, and caused them to oscillate in the magnetic meridian. The nickel needle performed ten oscillations in eighty-seven seconds, and the steel one the same number in forty-five and a half seconds. As the shape of the needles was the same, the momenta of their directive forces were directly as their weights, and inversely as the squares of eighty-seven seconds and forty-five and a half seconds, that is, as 0·3088 to 1, that is, the directive force of the needle of nickel was *nearly one third* of that of the steel needle. Now it is impossible to suppose that purified nickel could contain such a large proportion of iron as is necessary to produce such a degree of magnetic polarity, without its being easily recognised by the chemist; and M. Biot supposes that the magnetic power of the nickel might have been still farther increased by the means which are used to modify the coercive power of steel and iron.

Brass.

A series of careful experiments were made by M. Cavallo, on the magnetism of *brass* when hammered. He found that brass, whether old or new, British or foreign, was made magnetic when placed between two pieces of card and hammered on an anvil with a common hammer; and that the magnetism thus imparted was always removed by making the brass red hot, and could be again communicated to it. Lest it might be supposed that ferruginous matter might pass to the brass through rents or openings in the card, he hardened a piece of brass by beating it between two large flints, using one piece as a hammer, and the other as an anvil. The hammered brass became magnetic, but not so strongly as before; which arose probably from the rough and irregular surfaces of the flints, which prevented the brass from being hardened as uniformly as it was with the steel hammer. The flints, before and after the experiment, did not possess the slightest magnetism.

The degree of magnetism communicated to brass by hammering is vaguely stated by Cavallo to have been such "as to attract either pole of the needle from about a quarter of an inch distance." The following are the conclusions which M. Cavallo has drawn from these and other experiments:

"1*st*, That most brass becomes magnetic by hammering, and loses its magnetism by annealing or softening in the fire, or at least its magnetism is so far weakened by it, as afterwards to be only discoverable when set to float on quicksilver.

"2*d*, The acquired magnetism is not owing to particles of iron or steel imparted to the brass by the tools employed, or naturally mixed with the brass.

"3*d*, Those pieces of brass which have that property, retain it without any diminution after a great number of repeated trials, viz. after having been repeatedly hardened and softened.

"4*th*, A large piece of brass has generally a magnetic power somewhat stronger than a smaller piece, and the flat surface of the piece draws the needle more forcibly than the edge or corner of it.

"5*th*, If only one end of a large piece of brass be hammered, then that end alone will disturb the magnetic needle, and not the rest.

"6*th*, The magnetic power which brass acquires by hammering has a certain limit, beyond which it cannot be increased by farther hammering. This limit is various in pieces of brass of different thicknesses, and likewise of different qualities.

"7*th*, Though there are some pieces of brass which have not the power of being rendered magnetic by hammering, yet all the pieces of magnetic brass that I have tried lose their magnetism, so as no longer to affect the needle, by being made red hot, excepting indeed when some pieces of iron are concealed in them, which sometimes occurs; but in this case the piece of brass, after having been made red hot and cooled, will attract the needle more forcibly with one part of its surface than with the rest of it; and hence, by turning the piece of brass about, and presenting every part of it successively to the suspended magnetic needle, one may easily discover in what part of it the iron is lodged.

---

[1] *Traité de Physique*, tom. iii. p. 126.

"8*th*, In the course of my experiments on the magnetism of brass, I have twice observed the following remarkable circumstance: A piece of brass which had the property of becoming magnetic by hammering, and of losing the magnetism by softening, having been left in the fire till it was partially melted, I found upon trial that it had lost the property of becoming magnetic by hammering; but having been afterwards fairly fused in a crucible, it thereby acquired the property it had originally, viz. that of becoming magnetic by hammering.

"9*th*, I have likewise often observed, that a long continuance of a fire so strong as to be little short of melting hot, generally diminishes, and sometimes quite destroys, the property of becoming magnetic in brass. At the same time the texture of the metal is considerably altered, becoming what some workmen call *rotten*. From this it appears, that the property of becoming magnetic in brass by hammering, is rather owing to some particular configuration of its parts, than to the admixture of any iron; which is confirmed still farther by observing that Dutch plate brass (which is made, not by melting the copper, but by keeping it in a strong degree of heat whilst surrounded by *lapis calaminaris*) also possesses that property, at least all the pieces of it which I have tried have that property. From these observations it follows, that when brass is to be used for the construction of instruments wherein a magnetic needle is concerned, as dipping needles, variation compasses, &c. &c. the brass should be either left quite soft, or it should be chosen of such a sort as will not be made magnetic by hammering, which sort, however, does not occur very frequently."

These judicious suggestions of M. Cavallo respecting the condition of the brass parts of azimuth compasses were not attended to as they ought, and we have no doubt that various grave errors have arisen from their neglect. Many examples have recently occurred, in which the errors were detected; and it is now the invariable practice of well-informed instrument-makers to reject hammered brass bowls for compasses, and to use those which are cast and turned for the purpose.

M. Cavallo and others have observed, that cobalt, zinc, copper, and bismuth, as well as their ores, are attracted by the magnet and antimony when gently heated. Minerals which are not metallic are almost all acted upon by the magnet, particularly where they have experienced the action of fire. The pure earths, and particularly silex, are found to have the same property. Among minerals, the following table shows those which are attracted and those which are not attracted by the magnet; but we place little faith in their accuracy.

Minerals not attracted.	Minerals attracted.
Diamond.	Oriental ruby.
Pellucid crystals.	Chrysolite.
Amethyst.	Tourmaline.
Topaz.	Emerald.
Calcedony, and other crystals whose colouring matter is expelled by heat.	Garnet.
	Several micas containing iron.

Some accurate experiments have been made on mica by M. Biot. The chemical composition and optical structure of different varieties of this mineral vary greatly. M. Biot examined particularly mica from Siberia and mica from Zinwald in Bohemia. Though both were highly pellucid, yet chemical re-agents indicated in each the existence of oxide of iron. In the Bohemian mica it was greatest, and, according to an accurate analysis by Vauquelin, amounted to 20 per cent. Before the Siberian mica was analysed, M. Biot tried their magnetic properties. He cut out of each, thin rectangular plates of the same form, which he subdivided into smaller similar pieces, and having united them in a bundle, he suspended each bundle by a silk fibre, and caused each bundle to oscillate in succession between the poles of two strong magnets. The bundle of Zinwald mica performed twelve oscillations in fifty-five seconds, and that of the Siberian mica only seven in the same time. Hence the magnetic powers of the two micas were as 6·8 to 20, the ratio of 49 and 14 to the squares of the number of oscillations. If the oxide of iron, then, be the cause of their magnetic virtue, it should exist in the above proportions of 6·8 to 20; and as it was found to be 20 per cent. in the Zinwald mica, it ought to be 6·8 in the Siberian. It is very remarkable that the result of Vauquelin's analysis gave exactly this per centage of the oxide of iron, though it was not known to M. Biot till his experiment had been made.

Magnetism of Bodies not Ferruginous.

Magnetism of combined metals.

The existence of magnetism in brass, while there was not the least trace of it either in the copper or zinc of which it is composed, led philosophers to investigate the effects produced by the union of different metals, or by their combination with other substances. *Iron* itself is a simple chemical body. *Steel* is a combination of iron and carbon. The *loadstone* is a combination of iron and oxygen; and as no magnetism is found either in carbon or oxygen, we are naturally led to believe, as M. Pouillet has remarked, that the magnetic fluid resides in the substance of the iron, and that it is carried with the atoms of that metal into all the chemical combinations which they form. We may therefore expect to find magnetic properties more or less developed in all ferruginous bodies, whether the iron be an accidental or an essential ingredient; and indeed cast iron, plumbago, and the oxides and sulphurets of iron, exert a sensible action on the magnetic needle.

Anti-magnetic bodies.

These views, however, are not in unison with facts which seem to have been well ascertained. Dr Matthew Young found, that the smallest admixture of antimony was capable of destroying the polarity of iron; and M. Seebeck states, that an alloy of one part of iron and four parts of antimony was so completely destitute of magnetic action, that, even when it was put into rotation, it exerted no power over the magnetic needle. The magnetic qualities of nickel also are destroyed by a mixture with it of other metals. Chenevix found that a very small proportion of arsenic deprived a mass of nickel which had previously exhibited a strong magnetic power, of the whole of its magnetism; and Dr Seebeck found that an alloy of two parts of copper with one of nickel was entirely devoid of magnetism, and on this account he recommends it as well suited for the manufacture of compass boxes. On the other hand, Mr Hatchet ascertained, that when a large proportion of *carbon*, or *sulphur*, or *phosphorus*, was combined with iron, the iron was enabled fully to receive and retain its magnetic properties; but he at the same time found that there was a limit beyond which an excess of any of these three substances rendered the compound wholly incapable of receiving magnetism.

Animal and vegetable substances, after combination, are said to be attracted by the magnet. The flesh, and particularly blood, are acted upon more powerfully than other parts, and bone less powerfully. Burned vegetables have the same property, and also soot and atmospheric dust; and M. Cavallo has maintained, that brisk chemical effervescence acted upon the magnetic needle.

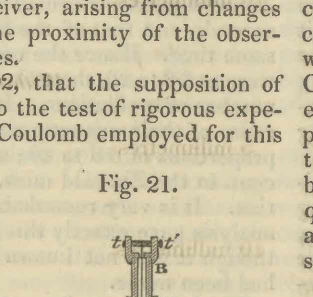
SECT. II.—*Account of the Experiments of Coulomb, Becquerel, Arago, and Seebeck, on the Existence of Universal Magnetism.*

Universal magnetism.

These various experiments on the magnetic power of so many classes of bodies, differing essentially in their composition, and in many of which it could not be reasonably supposed that iron existed, led some philosophers to believe that almost all substances gave indications of magnetism. M. Cavallo announced this opinion, but Mr Bennet questioned the accuracy of the experiments, and ascribed the movements observed in the needle to the agitation of the air in the receiver, arising from changes of temperature produced by the proximity of the observer's body, or from other causes.

Coulomb's experiments.

Fig. 21.



It was not therefore till 1802, that the supposition of universal magnetism was put to the test of rigorous experiment. The apparatus which Coulomb employed for this purpose is shown in fig. 21, where AA is a glass receiver perforated at its top, and having a tube A′B, with a cork B, which could be raised and lowered with facility. Through this cork passed a rod *tt* of wood or metal, to which was attached a silk fibre, which suspended a ring of very fine paper, on which the small needle *ns* (about the third of an inch long and $\frac{1}{30}$th thick) was placed. The receiver was then placed so as to enclose the opposite poles N, S of the powerful magnets M, M, each formed of four bars of steel tempered to a white heat. Each bar was seventeen inches long, three fifths of an inch wide, and one sixth of an inch thick, each bundle of four bars being one and three eighths of an inch wide, and one third of an inch thick. The distance N S of their poles was eight tenths of an inch. In making the experiments, the rod *tt* was turned till the needle *ns* was removed from the influence of the magnets; and after the number of its oscillations was observed, the rod *tt* was turned till the needle descended between the poles N, S of the magnets, when the number of oscillations of the needle was again counted, or the time in which a given number of oscillations was performed. If the needle performed the same number of oscillations in the same time, whether it oscillated between the poles N, S, or beyond their influence, it is obvious that the magnets exercised no power over them; but this was never the case, and Coulomb found that all substances whatever, when formed into small needles, turned themselves in the direction of the poles N, S, and, after a few oscillations, finally settled in that position. When these bodies were moved a very little way out of their position of equilibrium, they immediately began to oscillate round it, the oscillations being always performed more rapidly in the presence of the magnets than when they were removed out of their influence. Gold, silver, glass, wood, and all substances, whether organic or inorganic, thus obey the power of the magnets. Hence we cannot avoid the conclusion, either that all bodies are susceptible of magnetism, or that they contain minute quantities of iron, or other magnetic metals, which give them that susceptibility. M. Biot does not consider this alternative so inevitable as it appears, and throws out the conjecture, that the action may not be magnetic, but may be owing to some small force similar or analogous to the electrical forces developed by the simple contact of heterogeneous bodies. This no doubt might be, if there was any contact; and, in the absence of any reasons whatever for ascribing the observed effects to another cause, we cannot but rest between the alternative opinions above mentioned, giving a preference to that which ascribes the phenomenon to the existence in all bodies of a slight susceptibility to magnetic action.

This opinion derives considerable support from the experiments made by Coulomb on the comparative magnetic susceptibilities of cylindrical needles of gold, silver, lead, copper, and tin, which had been purified with the greatest care by MM. Sage and Guyton, and the results of which we have already given in our history of magnetism. M. Coulomb made a number of experiments on the effects experienced by needles of white wax, containing different proportions of iron filings, and he found that the intensities of the action which they experienced when oscillating between two magnets, was proportional to the absolute quantities of iron which they contained, the distribution and chemical state of the ferruginous particles being the same.

Since the time of Coulomb, methods different from his have been employed in developing magnetism in all bodies whatever. In order to detect small quantities of iron in minerals, M. Haüy employed the process of what he calls *double magnetism.* For this purpose, he placed a small bar-magnet in the direction of the needle, and in the same horizontal plane, the two similar poles being placed towards each other. The magnet being now brought slowly towards the needle, the latter deviates from the direction of the magnetic meridian, and takes a position perpendicular to it; an effect arising from the combined action of the poles of the magnet and the earth upon the magnetism of the needle. In this position, *a very feeble magnetic action* is sufficient to make the needle turn round and place its south pole opposite the north pole of the needle.

When the magnet is above the plane of the needle, and their opposite poles placed near each other, the needle does not change its direction while the point of suspension is beyond the bar, and at a suitable distance; but it is not so when the distance changes, for it tends continually to place itself perpendicular to the line of the poles.

Researches of M. Becquerel.

This important subject has been investigated by M. Becquerel, who obtained the following results.[1] His bar-magnet consisted of six united bars, each eight decimetres long and two centimetres broad. The needle was placed at different heights within and without the bar, and he sought to determine for each height the horizontal distance from the point of suspension (which is always in the line of the poles) to the nearest extremity of the needle, in order that its direction might be perpendicular to that line. The results were as follow:

Vertical Distances from the Centre of Suspension to the Bar.	Horizontal Distances of the Centre of Suspension to the Extremity, in order that the Needle might take a perpendicular position.
Millimetres.	Millimetres.
100	60 within.
150	55
200	46
250	23
300	12
350	45 without.
400	82

Hence it appears, that when the centre of suspension is above the bar, the perpendicular position is obtained by increasing the vertical and diminishing the horizontal distance; and that both these distances are increased while the centre of suspension is below the bar; and the direction of the deviation depends on accidental causes, and is often determined by the simple motion of the apparatus.

---

[1] *Traité Exp. de l'Electricité, &c.* tom. ii. p. 387.

When M. Becquerel substituted for his magnetic needle a needle of soft iron, the results were exactly the same, differing only in their intensity. We come now to the original part of M. Becquerel's inquiry. Instead of a needle he used a small paper case filled with *deutoxide of iron*, or a mixture of deutoxide and tritoxide. With the former the effects were the same as with the steel needle; but it was different with the latter, in which one part of deutoxide was mixed with thirty parts of tritoxide.

If the centre of suspension be placed as near as possible to the north pole of the bar-magnet, and in the line of the poles, the paper case will take immediately a direction perpendicular to this line, instead of one coincident with it, as a soft iron needle would have done. If we put it out of this direction, it will return to it by a series of oscillations, whose velocity depends on the quantity of the deutoxide. From this it follows, that *all the south polar magnetism of the paper case is situated on the side of it next the bar-magnet, while the north polar magnetism is on the other side*, as may be exhibited by carrying a small magnetic needle along the paper case. Such a distribution of magnetism is impossible in soft iron or tempered steel.

If the centre of suspension be above the bar, the paper case will deviate from the position which it had at first, and tend to place itself in the direction of the line of the poles; an effect quite opposite to that produced by a steel or iron needle. The following were the experimental results:

Vertical Distances of the Centre of Suspension from the Bar.	Horizontal Distances of the same Centre to one of the Extremities of the Bar.	Deviations of the Paper Case from the Direction perpendicular to the Line of the Poles.
10 millimetres,	5	24°

	15	73
	20	77
	30	32
30 millimetres,	5	70
	20	76
	30	82

The *transverse magnetism* acquired by the paper case is permanent for some time, however small may be the proportion of deutoxide which it contains.

M. Becquerel next filled the paper case with very pure tritoxide, obtained by calcining nitrate of iron. The effect was much weaker than before. When the point of suspension was very near one of the extremities of the bar, the paper case still placed itself in a position perpendicular to the line of the poles; but if this point was placed above or below the bar, changing at the same time the vertical distance, the paper case deviated from its primitive direction, without, however, taking a direction perpendicular to that which it commonly takes when the centre of suspension is very near the extremity. It might be possible, M. Becquerel thinks, to attain the perpendicular direction by employing much stronger magnets. The following were the experimental results:—

Magnetism of Bodies not Ferruginous.

Vertical Distances from the Point of Suspension to the Bar.	Horizontal Distances of the same Point from the end of the Bar.	Deviations from the Direction perpendicular to the Line of the Poles.
	Without the Bar.	
5 millimetres,	5	25°
	10	34
	15	48
	20	55
	25	70
10 millimetres,	5	32
	10	37
	15	43
	20	46
	25	40
	Within the Bar.

	15	...
	20	45
	25	51
10 millimetres,	10	20
	15	30
	20	45
	25	50

Whenever the tritoxide contains the smallest quantity of the deutoxide, the velocity of the oscillations increases very powerfully. If, for example, we take *two* paper cases, one filled with tritoxide, and the other with tritoxide mixed with one thirtieth of the deutoxide, the first will perform twelve oscillations in thirty seconds, round a direction perpendicular to the line of the poles, while the other will execute twenty-five in the same time. Hence we may by this means readily determine the quantity of the deutoxide of iron contained in the tritoxide.

With needles of wood, &c.

M. Becquerel next employed needles of wood, gum-lac, and other substances, which have still a feebler magnetism than the tritoxide of iron. He placed a needle of white wood, *n s*, four centimetres long and two millimetres in diameter, above the interval between the opposite poles of two bar-magnets, as in fig. 21, the distance between N and S being three or four millimetres. The point of suspension was as near as possible to N S. The needle placed itself perpendicular to the line of the poles N, S, in place of the position observed by Coulomb, coincident with N S. It comports itself therefore like the mixture of deutoxide and tritoxide of iron, or like the tritoxide alone. But if we separate gradually the extremities N, S of the bars, the wooden needle will place itself in the line N S, joining the poles, as shown in the figure. The deviations were as follow:

Distances of N, S.	Deviations of the Wooden Needle from the perpendicular position.
3 or 4 millimetres,	0°
10	18
20	36
30	56

When the bars are very close, and the needle in the perpendicular position, if we draw it out of this position, and keep it some instants in the direction of this line, it will remain there; but the smallest motion will cause it to return into its primitive direction, which it takes in preference to any other.

If we use only one bar-magnet, and place the wooden needle precisely opposite one of its poles, and as near as possible to the end of the bar, it will still direct itself perpendicularly to it; but if, while the point of suspension remains always in this line, we advance it within the bar, the needle will deviate from its direction, without, however, reaching the position of 90°, as will be seen from the following results:

Magnetism of Bodies not Ferruginous.

Distances of the Centre of Suspension from the Extremity of the Bar.	Deviations of the Wooden Needle.
5 millimetres,	12°
10	18

Beyond ten millimetres the deviations increase insensibly and irregularly, so that they cannot be measured.

General conclusion.

From these interesting experiments, M. Becquerel concludes that the magnetic effects produced by a strong bar-magnet upon a magnetic needle, or one of soft iron, differ essentially from those which take place in all bodies where the magnetism is very weak. In the former, whatever be their positions and directions, the magnetism is always distributed in the direction of their length, to the exclusion of every other direction; whereas in the tritoxide of iron, wood, and gum-lac, it is distributed in a direction which depends on the distance of the body from the poles of the magnet, so that the distribution varies with the direction which the magnet causes these needles to take, in virtue of the action which it exercises over them.

Discoveries of M. Arago.

The universal prevalence of magnetism in all bodies whatever has been established by a beautiful discovery of M. Arago. This distinguished philosopher conceived the idea of studying the oscillations of a magnetic needle when placed above or near any body whatever. Having suspended a magnetic needle above metal, or even water, and caused it to deviate a certain number of degrees from its position, it began, when left to itself, to oscillate in arcs of less and less amplitude, as if it had been placed in a resisting medium; and, what was peculiarly curious in these experiments, this diminution in the amplitude of the oscillations did not alter the number of oscillations which were performed in a given time. The following were some of M. Arago's experiments with *water*, *ice*, and *glass*, the semiamplitude of the oscillations being at the instant 43°.

The distance of the water from the needle was..0·65 millim.
The amplitude lost 10° in.....................30 oscillations.
When the distance was.......................52·2 millim.
A loss of 10° of amplitude required..........60 oscillations.

That is, the number of oscillations required to diminish the amplitude 10° was twice as great when the distance of the needle from the water was 52·2 millimetres, as when it was 0·65.

By placing the same needle upon ice, M. Arago obtained the following results:

Distances of the Needle from the Ice. Millimetres.	Diminution of the Amplitude.	Number of Oscillations by which this diminution was effected.
0·70	From 53° to 43°	26 oscillations.
1·26	From 53 to 43	34
30·50	From 53 to 43	56
52·20	From 53 to 43	60

By placing another needle near a plate of crown glass, he obtained the following results:

0·91	From 90° to 41°	122
0·99	From 90 to 41	180
3·04	From 90 to 41	208
4·01	From 90 to 41	221

Plates of metal afforded M. Arago similar results; but he nevertheless observed that those metals which act with more energy than glass, wood, &c. have a mode of action different from that of these substances. From all these results, it is manifest that all bodies, when placed near a magnetic needle in a state of oscillation, exercise over it an action, the effect of which is to diminish the amplitude of its oscillations, without altering their number; and hence the doctrine of the universal prevalence of magnetism in all bodies derives a new confirmation.

Development of Magnetism in all Bodies by Rotation.

When Dr Seebeck of Berlin heard of the discovery of M. Arago, he made a magnetic needle two and an eighth inches long oscillate at a distance of three lines above plates of various bodies, and counted the number of oscillations which were required in each case to reduce the amplitude from 45° to 10°.

Substances employed.	Thickness of the Plates.	Number of Oscillations of the Needle.
Marble	0·0 line	116 oscillations.
Mercury	2·0	112
Bismuth	2·0	106
Platina	0·4	94
Antimony	2·0	90
Lead	0·75	89
Gold	0·2	89
Zinc	0·5	71
Tin	1·0	68
Brass	2·0	62
Copper	0·3	62
Silver	0·3	55
Iron	0·4	6

Dr Seebeck found, that in alloying magnetic with non-magnetic substances, he formed *compounds which exercised no action on the magnetic needle.* The alloys which had particularly this singular property were those consisting of four parts of antimony and one of iron, or two parts of copper and one of nickel. In these cases the magnetism of the two ingredients must have been neutralized by their opposite actions.

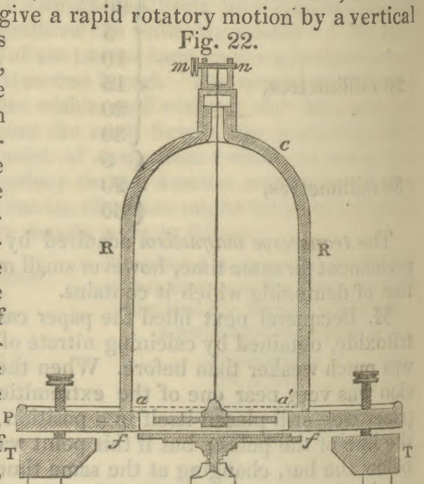
CHAP. IV.—ON THE DEVELOPMENT OF MAGNETISM IN ALL BODIES BY ROTATION.

M. Arago's experiments.

When M. Arago was engaged in the experiments described in the preceding chapter, the idea occurred to him of trying if the magnetic needle would be dragged along by the rotatory plates which had the power of diminishing the amplitude of its oscillation. This happy conjecture was immediately confirmed by experiment, and one of the most beautiful discoveries added to the science of magnetism.

The apparatus which he used for this purpose is shown in Plate CCCXXV. fig. 3, where H is a clock made of copper, with the exception of two or three pivots, which are of steel. It is supported on a tripod stand TT, which can be levelled by screws S, S at the end of its three feet; and the object of it is to give a rapid rotatory motion by a vertical axis, on which is fitted a piece *a*, *b*, *c*, fig. 4, with three branches, upon which the revolving discs are to be placed. These discs are perforated at their centre by a small hole which receives the prolongation of the axis of rotation, and they are kept upon the branches *a*, *b*, *c*, by the pressure of a screw. Wings *w*, *w*, *w* (fig. 4), which can be inclined at any angle, are applied for the purpose of retarding the velocity of the discs. A plate PP, with an opening in its centre a little larger than the diameter of the discs, rests upon the table TT, and a sheet of paper *f f*, shown in fig. 22 (which is an enlarged view of that part of the apparatus),

Fig. 22.



is pasted to the lower face of PP. A glass receiver RR rests upon the upper face of PP, and within it is suspended the magnetic needle *aa′*, by a fibre of silk attached to the axis and button *mn*, by which the needle can be raised or depressed. A weight W gives motion to the clock, and a hand indicates upon the dial-plate the number of revolutions performed by the disc in a given time.

When a disc of copper was placed on the support *a*, *b*, *c*, Plate CCCXXV. fig. 4, as shown at PP, fig. 22, and the copper made to revolve beneath the needle *aa′*, with the sheet of paper *ff* intervening, the needle *aa′* is drawn out of the magnetic meridian the instant that the copper begins to revolve, and with a degree of force proportional to the velocity of rotation. As the force with which the needle s dragged from its place is opposed to the magnetic action of the earth, which tends to keep the needle in the magnetic meridian, the needle will take a position of equilibrium depending on the ratio of these forces. When the motion of the copper disc, however, is very rapid, the magnetism of the earth is overpowered by that of the revolving plate, and the needle does not stop, but continues o turn. The action of the revolving disc decreases in proportion as the distance of the needle from the plate PP is increased, the velocity being the same; so that if he motion of the needle be continuous when the two bodies are separated only by a sheet of paper, the needle will take a fixed position by increasing its distance from he plate; and its deviation from the magnetic meridian becomes less and less as it is removed to a greater height above the disc. When the plates have portions cut out n the direction of their radii, their action on the needle is diminished.

In trying plates of various metals, M. Arago found the results so dependent on the alloy which the metals conained, that he did not publish the results which he obained. He devoted his attention to the determination of he directions of the force which is developed in the revolving discs, and for this purpose he sought the components of this force in the direction of three lines parallel to three co-ordinate planes perpendicular to each other. The *component* perpendicular to the plate he found to be a repulsive force, which may be rendered sensible by means f a very long magnet suspended by a thread vertically to he extremity of the arms of a balance kept in equilibrium y a weight at the other extremity. The moment that he plate begins to revolve, the magnet is repelled, and the eam of the balance inclines to the other side. The *seond* component is horizontal and perpendicular to a verical plane which contains the radius abutting against the projection of the pole of the needle. This is the force which gives a motion of rotation to the needle, and it acts n the direction of a tangent to the circle. The *third* component is parallel to the radius which abuts against he projection of the pole of the needle. It may be deermined with a dipping needle placed vertically, so that s axis of rotation is continued in a plane perpendicular o one of the radii of the disc. A similar needle placed t the centre of the disc experiences no action. There is also a second point, nearer the margin than the centre, here a needle experiences no change in its position; but etween these points the lower pole is constantly attracted towards the centre, while it is repelled beyond that point.

Development of Magnetism in all Bodies by Rotation.

No sooner were M. Arago's experiments announced to the Institute, which was done at the sitting of the 7th March 1825, than philosophers in every part of Europe repeated them, and succeeded in adding several important facts to those discovered by M. Arago. MM. Babbage, Herschel, Barlow, Nobili, Baccelli, Christie, and MM. Prevost and Colladon, took a prominent part in these researches. The results obtained by Messrs Babbage and Herschel were the most important, and the experiments were made in a manner different from those of M. Arago. A horse-shoe magnet, which lifted twenty pounds, was made to revolve rapidly round its axis of symmetry, placed vertically, with its poles uppermost. A circular disc of copper, six inches in diameter and $\frac{1}{24}$th of an inch thick, was suspended above the revolving magnet. As soon as the rotation of the magnet commenced, the copper began to turn in the same direction, at first slowly, but afterwards with an increasing velocity. When the magnet was made to turn in the opposite direction, the disc of copper changed the direction of its motion also, and exhibited the same phenomena. Metallic plates, ten inches in diameter and half an inch thick, when interposed between the magnet and the copper disc, did not sensibly modify the results, as M. Arago had observed. Glass produced no effect, but a sheet of tin-plate iron diminished greatly the influence of the magnet, while two such plates almost destroyed it. They also found that a disc of copper ten inches in diameter, and half an inch thick, and revolving with a velocity of seven revolutions in a second, did not communicate any motion to a similar disc freely suspended above it.

Experiments of Messrs Babbage and Herschel.

In comparing the influence of different metals, each disc had the same diameter and the same velocity; and the following were the results which were obtained by this and another method of observation.

	Ratio of the Force to that of Copper.	Ratio by another Method.
Copper	1·00	1·00
Zinc	0·90	1·11
Tin	0·47	0·51
Lead	0·25	0·25
Antimony	0·11	0·01
Mercury	0·00	0·00
Bismuth	0·01	0·00
Wood	0·00	0·00

The second method of observation by which the results in the last column were obtained was more expeditious than the first. Portions of different bodies of the same form and dimensions were suspended above a revolving magnet, and the time of successive oscillations and the points of equilibrium were observed.

Our authors next sought to determine the effect produced by a solution of continuity in the metallic disc upon which the revolving magnet acted. For this purpose a disc of lead twelve inches in diameter and one tenth of an inch thick was suspended at a given distance from a horse-shoe magnet revolving with the ordinary rapidity, first in its entire state, and afterwards in the state shown in the annexed figures, the black lines in the direction of the radii be-

Fig. 23.

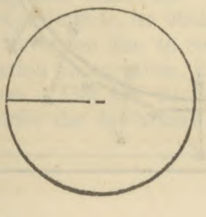


Fig. 24.

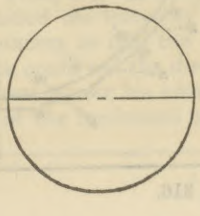

Fig. 25.

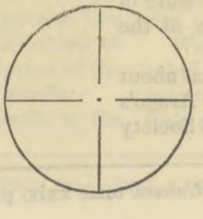

Fig 26.

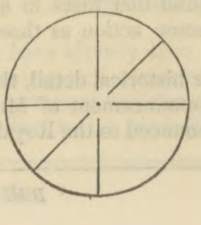

Fig. 27.

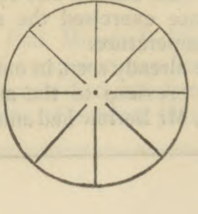


Development of Magnetism in all Bodies by Rotation.

ing the planes where the lead was cut through. The accelerating forces, represented by $\frac{s}{t^2}$, where s is the number of the revolutions, and t the time employed, are as follow:

Uncut Disc.	Disc as in fig. 23.	Disc fig. 24.	Disc fig. 25.	Disc fig. 26.	Disc fig. 27.
1258	1047	913	564	432	324

Effects similar, but differing in degree, were obtained with other metals. With soft tinned iron the cutting produced a very slight diminution of effect, whilst in copper the same operation reduced the accelerating force in the ratio of five to one.

Messrs Babbage and Herschel next tried the effect of filling up the cuts with other metals. A light upper disc, suspended at a given distance above a revolving magnet, performed six revolutions in 54″·8. When it was cut as in fig. 27, its magnetic action was so weakened that it took 121″·3 to perform six revolutions. When the eight open radial spaces were filled up with tin, its magnetic action was restored to such a degree that it made six revolutions in 57″·3. This fact is very interesting, as tin has less than half the energy of copper. The following results were obtained from other experiments, the numbers representing the accelerating forces or the magnetic energies developed in the plates.

Brass not cut	1·00
Brass cut	0·24
Brass soldered with bismuth	0·53
Brass soldered with tin	0·88
Copper not cut	1·00
Copper cut	0·20
Copper soldered with tin	0·91

Law of the force.

In determining the law of the force in relation to the distance, Messrs Babbage and Herschel found it to vary between the ratio of the square and the cube of the distance. Mr Christie found, that when the revolving disc was thick and the needle delicate, the force which produced the deviation of the needle increased directly as the velocity of rotation, and inversely as the fourth power of the distance. MM. Prevost and Colladon found that the angles of deviation, and not their sines, increased in the direct ratio of the velocity, at least within certain limits; and that the sines of the angles of deviation were in the inverse ratio of the two and a half power of the distance.[1]

Experiments of M. Haldat;

M. Haldat made some interesting experiments on this subject. He found that every needle, however weak was its magnetism, obeyed the action of the revolving disc; but that this action disappeared entirely when its polarity disappeared. He found it impossible to magnetise needles by the action of the revolving disc, however rapid; and, in consequence of ascribing this effect to the want of coercive power, he employed discs of iron and steel, both soft and hardened.

A disc of soft iron acted with more energy than one of copper, and with the same velocity it dragged the needle twice the distance that a disc of brass did. Iron strongly hammered acted like soft iron, and was unable to give polarity to a steel needle. But a disc of untempered steel one twenty-fifth of an inch thick did not produce any appreciable effect on the magnetic needle, which, after a few irregular oscillations, maintained its ordinary position of equilibrium. Hence our author concluded that the force which acted upon it was in the inverse ratio of the coercive force. M. Haldat also found that discs in a state of incandescence exercised the same action as those at the ordinary temperature.

of Mr Barlow.

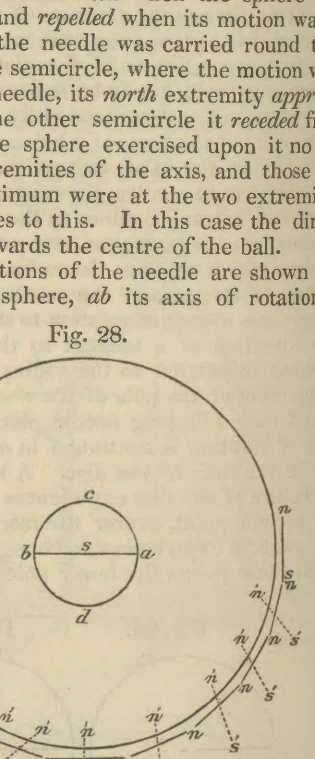
We have already seen, in our historical detail, that about six months previous to the announcement of M. Arago's discoveries, Mr Barlow had announced to the Royal Society of London the result of a series of experiments on the magnetic effects produced by iron in rotation. Having found that an iron ball performing 640 revolutions in a minute caused a magnetic needle to deviate several degrees, and to take a fixed position during the continuance of the motion; that the needle deviated in an opposite direction when the motion of the ball was reversed; that there were certain positions in which a bomb twelve inches in diameter, moved by a steam-engine, occasioned no deviation in the needle; that in some positions the deviation was in one direction, and in other positions in another; and that the deviation varied between 0° and 80°; he constructed a regular apparatus for determining the laws of these phenomena, and in which the iron which formed part of it should not influence the results. This apparatus is shown in Plate CCCXXV. fig. 2, where S is an iron sphere, made to revolve on a horizontal axis AB, by means of two wheels, like an electrical machine, their diameters being as six to one, so as to perform 720 revolutions in a minute. A table LM was placed near the sphere, for holding the needle, so that the needle could be placed in any position, either above or below the sphere. The table LM being brought to the height of the axis AB, the needle was placed successively in different positions round the sphere. The influence of the earth's magnetism on the needle being destroyed or neutralised by the action of a magnet properly placed for this purpose, and shown at NS standing vertically, Mr Barlow found, that whatever was the azimuth of the needle, its *north pole* approached the sphere S when the upper part of the sphere was moving *towards* the needle, and that its *south pole* approached the sphere when the upper part moved *from* the needle.

Development of Magnetism in all Bodies by Rotation.

Having placed the axis of rotation sometimes in the magnetic meridian, sometimes in the direction of east and west, and sometimes in intermediate positions, he found, that whatever was the direction of the axis of rotation, the needle being always a tangent to the sphere, the *north* end of the needle was *attracted* when the sphere moved *towards* the needle, and *repelled* when its motion was *from* the needle. When the needle was carried round the revolving sphere in the semicircle, where the motion was directed towards the needle, its *north* extremity *approached* the sphere, and in the other semicircle it *receded* from it. The points where the sphere exercised upon it no action were at the two extremities of the axis, and those where the effect was a maximum were at the two extremities of an axis at right angles to this. In this case the direction of the needle was towards the centre of the ball.

The different positions of the needle are shown in fig. 28, where *s* is the sphere, *ab* its axis of rotation, and

Fig. 28.



---

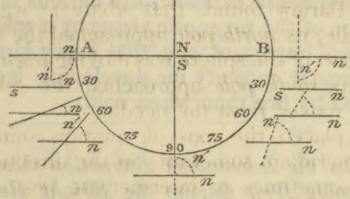
[1] *Bibl. Univers.* tome xxix. p. 316.

ed its equator. The lines *ns*, *ns*, &c. show the primitive position of the needle, and the dotted lines *n's'*, *n's'*, &c. those assumed by it when the motion is made from *c* to *d*. The effects are reversed when the motion is made from *d* to *c*.

If we carry the needle, when perfectly neutralised, round the sphere, and parallel to its axis, it has a tendency to place itself at right angles to the axis, and takes opposite directions at certain parts of the circle. If, for example, the axis be in the magnetic meridian, and the motion directed from the west to the east point of the horizon, the needle will direct itself to the west, and will do the same at all points between the horizon and an altitude of 60°. Beyond this the north end will direct itself to the east till it has passed the zenith 30° to the west; and then from this point to the west horizon, the north extremity will direct itself to the west, and similar changes will take place under the sphere. The same effects are produced, whatever be the direction of the axis and that of motion.

When a magnetic needle *not neutralised* is placed in different positions round the sphere whose axis is in the magnetic direction, the effects produced are as shown in fig. 29, where AB is the axis of rotation, the black lines representing the natural deviations of the needle, and the dotted ones those which it assumes when the sphere is in motion. Beginning at the point A, if the motion be from left to right, that is, from west to east, the needle moves from *n* to *n'* in the same direction till it arrives at 30°. It then remains in its natural direction. The needle moves in a contrary direction from right to left at 60°, 75°, and at 90°.

Fig. 29.



Mr Barlow was next desirous of ascertaining the different effects produced by a solid and a hollow ball of iron, and with this view he put in motion a solid ball 7·87 inches in diameter, and weighing sixty-eight pounds, and also a hollow sphere of iron, weighing only about thirty-four pounds. Both of them performed 640 revolutions in a minute, and the following were the average results:—

		Weight.
Mean deviation of the solid ball..........	28° 24'.......	68 lbs.
Mean deviation of the hollow ball......	15 5	34

When the two balls were at rest, the difference of their action was nothing.

Mr Barlow's paper on rotation was communicated to the Royal Society on the 14th April 1825, and on the 20th Mr Christie communicated one *On the Magnetism of Iron arising from its Rotation.* Mr Christie's experiments were made with circular plates of iron put in motion by an ingenious piece of machinery, by which he could make the plate revolve in every possible plane in reference to the magnetic meridian. From a great body of well-devised experiments, he obtained the following general law of the deviation due to rotation, so that the direction of the rotation being given, he could tell the direction of the deviation. This law we must give in his own words.

"I refer the deviations of the horizontal needle to the deviations of magnetic particles in the direction of the dip, or to those of a dipping needle passing through its centre; so that, in whatever direction this imaginary dipping needle would deviate by the action of the iron, the horizontal needle would deviate in such a manner as to be in the same vertical plane with it: thus, when the north end of the horizontal needle deviates towards the west, and consequently the south end towards the east, I consider that it has obeyed the deviation of the axis of the imaginary dipping needle, whose northern extremity has deviated towards the west, and its southern towards the east; so that the western side of the equator of this dipping needle has deviated towards the south pole of the sphere, and its eastern side towards the north pole. It would follow from this, that if the north and south sides of the equator of the dipping needle (referring to these points in the horizon) deviated towards the poles, no corresponding deviations would be observed in the horizontal needle; the effect, in this case, taking place in the meridian, would only be observable in the angle which the dipping needle made with the horizon. As it is not my intention at present to advance any hypothesis on the subject, I wish this to be considered only as a method of connecting all the phenomena under one general view. Assuming it then for this purpose, it will be found that the *deviations of the horizontal needle due to rotation* are always such as would be produced *by the sides of the equator of this imaginary dipping needle deviating in directions contrary to the directions in which the edges of the plate move*, that edge of the plate nearest to either edge of the equator producing the greatest effect on it."

Development of Magnetism in all Bodies by Rotation.

From another set of experiments, Mr Christie also found that the effect produced on the iron by its rotation is permanent so long as the plate remains stationary; that it is independent of friction; that it is so far independent of velocity, *that the iron can scarcely be moved so slowly that the whole effect shall not be produced; and that the whole effect is produced by making it perform one fourth of a revolution.* After Mr Christie had discovered these peculiar effects, he exhibited some of the phenomena to Mr Barlow, who conceived that the effect would be increased by rapid rotation, and who was thus led to make the experiments of which we have already given an account; but the phenomena differ essentially from those observed by Mr Christie, the former being temporary and dependent on velocity, while the latter are permanent, and independent of the rapidity of rotation.

In comparing the magnetic forces produced by rapid and slow rotation, Mr Christie found that the forces exerted on the needle during the rapid rotation of the plate are always in the same direction as the forces which are derived from the slowest rotation, and which continue to act after the rotation has ceased; but that the former forces are greater than the latter. From a mean of all the observations, the forces seem to be in the ratio of seventeen to thirteen, or very nearly of three to two. Hence Mr Christie conceives that the polarising of the iron in the same direction will account for the phenomena in both cases; but that the intensity of the polarity during the rapid rotation is greater than of that which appears to be permanent after the rotation, whether slow or rapid, has ceased; and that the phenomena observed during rapid rotation are such as should be expected from what have been described as arising from rotation, without regard to its velocity.

Experiments of Mr Snow Harris.

We have already seen that Messrs Babbage and Herschel interposed plates of various metals between the revolving magnet and the copper disc, and found no perceptible effect to be produced. Mr Snow Harris,[1] however,

---

[1] *Phil. Trans.* 1831, p. 497.

Influence of Heat on Magnetism.

has recently shown that several substances not supposed to contain iron have the power of intercepting the influence of a revolving magnet. A circular magnetic disc being delicately balanced on a fine central point by means of a rim of lead, was put into a state of rotation on a small agate cup, at the rate of 600 revolutions in a minute; and a light ring of tinned iron, also finely balanced on a central pivot, was placed immediately over it, at about four inches distance, by means of a thin plate of glass, on which its pivot rested. When the ring of tinned iron began to move slowly on its pivot by the influence of the magnet revolving below, a large mass of *copper*, about *three* inches thick, and consisting of plates a foot square, was carefully interposed between the magnet and the iron ring. The interposition of the copper soon sensibly diminished the motion of the iron disc, and at length *arrested it altogether.* On again withdrawing the copper, the motion of the disc was restored; and the same effects were repeatedly obtained. In this experiment both the magnet and the disc were enclosed by glass shades, and supported on a firm base.

The same effects were produced by a mass of silver and zinc; but when their thickness was considerably diminished by removing the central plates, the motion of the disc was not impeded. A very great thickness of *lead* was necessary to stop the disc, in consequence, as Mr Harris supposes, of its magnetic energy being so much less than that of copper.

CHAP. V.—ON THE INFLUENCE OF HEAT ON MAGNETISM.

Influence of heat on magnetism.

This interesting department of magnetism divides itself into three parts: 1*st*, On the effect of heat on the development of free magnetism; 2*dly*, on the anomalous attraction observed during the bright red and red heats; and, 3*dly*, on the effect of heat on the distribution of magnetism in magnets.

SECT. I.—*On the Effect of Heat on the development of Magnetism in Cast and Malleable Iron.*

In cast and malleable iron.

In the course of his experiments on the relative magnetic powers of different kinds of iron and steel, already given in the history of magnetism, Mr Barlow was led to the conclusion, that the harder the metal was, the less it exhibited of a magnetic quality; a result which was highly favourable to the hypothesis, that the cohesive power of hardened steel not only prevented the entire development of its magnetism, but also the re-combination of the two kinds of magnetism when they were displaced by the action of a powerful magnet. With the view of establishing this hypothesis, Mr Barlow found it necessary to ascertain whether these different kinds of iron and steel would exhibit the same magnetic powers when reduced to the same degree of softness, which could only be done by heating them in a furnace, and trying their magnetic qualities in that state.

Having procured a bar of soft iron twenty-five inches long and an inch and a quarter square, and a cast-iron one of nearly the same dimensions, he inclined the bars in the direction of the dip; and having placed a magnetic needle nearly on a level with the upper extremity, and at the distance of six inches from it, he observed the deviations produced by the bars in different states of heat. Thus,

Influence of Heat on Magnetism.

Cast iron	Cold	Mean deviation	21°	30′
Ditto	White heat	Ditto	0	0
Ditto	Blood-red heat	Ditto	62	0
Malleable iron	Cold	Ditto	40	0
Ditto	White heat	Ditto	0	0
Ditto	Blood-red heat	Ditto	55	0

These experiments were often repeated with the same results. It deserves to be remarked as a singular result, that cast iron is decidedly inferior in its action when cold, and when hot possesses a superior power to malleable iron.

Mr Barlow now compared malleable iron with soft and hard shear steel. The bars were twenty-four inches long and an inch and a quarter square, and the following were the results:

Malleable iron	Cold	Mean deviation	15°	10′
Ditto	White heat	Ditto	0	0
Ditto	Blood-red	Ditto	41	11
Soft shear steel	Cold	Ditto	11	0
Ditto	White heat	Ditto	0	0
Ditto	Blood-red	Ditto	48	0
Hard shear steel	Cold	Ditto	8	0
Ditto	White heat	Ditto	0	0
Ditto	Blood-red	Ditto	47	30

These experiments establish the curious fact of the total destruction of the magnetic virtue by a *white heat;* and also the no less important one, that every kind of iron or steel has a greater capacity for developing its magnetism when softened by fire than when cold.

SECT. II.—*On the Anomalous Attraction observed in Cast and Malleable Iron during the Bright Red and Red Heats.*

Anomalous attraction of iron at a red heat.

In pursuing the preceding researches, Mr Barlow was led to observe a remarkable anomaly in the action of the iron at the red heat. When iron brought to a white heat has wholly lost its power, it again acquires, as it passes into the bright red and red, a magnetic power; but, what is truly strange, its power is *attractive* for the south end of the needle; that is, if the *north* pole of the needle was attracted when the iron was cold, the *south* end will be attracted when the iron is at a bright red heat.

In order to investigate this subject thoroughly, Mr Barlow made a very extensive series of experiments with four different bars, each twenty-five inches long and an inch and a quarter square, two of them being of cast and two of malleable iron. He used also other two bars, one of cast and one of malleable iron, of the same dimensions, which were kept as standards to determine the quantity of cold attraction. The time employed in each experiment was a quarter of an hour: the white heat generally continued about *three* minutes when the negative attraction commenced. This attraction lasted about *two* minutes more, when the usual attraction began. This sometimes reached its maximum with great rapidity, but at other times it increased very gradually. The following table contains the results of Mr Barlow's experiments. The letters CB denote the cast-iron bar, and MB the malleable-iron bar; and the sign + indicates when the ordinary attraction of the iron takes place; and — the anomalous or negative attraction.

Influence of Heat on Magnetism.

Table of the Results of Mr Barlow's Experiments on the Effect of Iron on the Compass Needle at different Degrees of Heat.

N. B.—We have omitted the column for white heat, as no effect is ever produced at that temperature.

No.	Description of Bar.	Height and Depth of Centre of Bar from Needle.	Distance of Bar from Needle.	Position of Needle.	Effect when *Cold.*	Effect of *Red Heat.*	Effect at *Blood-Red Heat.*	Remarks.

38	M. B. No. 2.	0·0	4·7	North.	0 0	0 0	0 0	No motion in the needle.

Influence of Heat on Magnetism.

One of the most remarkable results of these experiments is, that the anomalous action of the bar between a bright-red and blood-red heat *increases* as we raise the bar above the needle, and becomes a *maximum* at the centre of the bar; whereas at low temperatures the action of a bar of iron under the very same circumstances goes on diminishing as the bar is raised, and becomes a minimum at the centre. When the needle is placed at the height of the centre of the bar, when heated to produce the anomalous effect, the smallest displacement is sufficient to change the sign and the quantity of the deviation.

Anomalous action of red-hot iron.

Mr Barlow made some experiments with a twenty-four pound ball of iron, but the heat was too intense to allow any very accurate observations to be made. The results, however, were as follow:

Cold attraction	+ 13°	30′	deviation.
Red heat	— 3	30	
White heat	0	0	
Blood-red heat	+ 19	20	

No effect whatever was produced on the needle by heated bars of copper.

In order to explain the singularly anomalous action above described, Mr Barlow supposes, that during the cooling of the bars, the extremities where this cooling is most rapid become magnetic before the rest of the metal, and that there results from this a complex action. He allows, however, that this supposition does not sufficiently explain all the observed phenomena. The explanation given by Professor Kupffer is more satisfactory. In weakly magnetised bars the points of indifference are very near the extremities; but in Mr Barlow's experiment the magnetism communicated to soft iron by the earth being nothing at a bright-red, and reaching its maximum at a blood-red heat, there is probably formed a point of indifference at each extremity of the bar. If this is the case, the raising of the bar places the needle in front of points which are beyond the point of indifference, and which possess a magnetism opposite to that of the extremity itself. At the first epoch of cooling, this opposite magnetism should even increase to a certain point, and the more as we approach the middle of the bar; but in proportion as the magnetism of the bar increases, the point of indifference will approach its middle, and the phenomena of ordinary attraction re-appear.

M. Kupffer's explanation.

SECT. III.—*On the Effects of Heat on the Distribution of Magnetism in Magnets.*

Effect of heat on the distribution of magnetism.

M. Coulomb was the first philosopher who investigated the important subject of the influence of heat on the distribution of magnetism, in needles and magnets.[1] He took a bar of steel 162 millimetres long, fourteen wide, and weighing eighty-two grammes. This bar was brought to a cherry-red heat, about 900°, and cooled slowly in the air, so as to have no temper. It was then magnetised to saturation at the temperature of about 12° Reaumur. In this state the time of making *ten* oscillations was observed. Its temperature was again raised successively so many degrees, and, after being cooled, the time of performing ten oscillations was again measured. The following were the results:

Temperature in degrees of Reaumur.	Time of performing Ten Oscillations.
12°	93″
40	97·5
80	104
211	147
340	215
510	290
680	very great.

Hence it is obvious that the magnetic intensity of the bar diminishes rapidly as its temperature is raised.

From another set of experiments Coulomb concludes that the tempering of a bar previous to its being magnetised has no influence until the heat at which it is tempered becomes about 750°. When the tempering is at 900°, the bar will take double the magnetic force that it did at 12°; the ratio of the time of ten oscillations being 63″ and 93″, the squares of which, to which the magnetic forces are proportional, are nearly as one to two.

After the magnet had received the hardest temper at 950°, it was magnetised to saturation. When it was brought back, by annealing, to lower temperatures, and again magnetised, the effects were as follow:

Temperature.	Time of *Ten* Oscillations of a Bar tempered at 95°.
12°	63″
80	66
214, blue colour	80
410, colour of water	170

Hence we see that the progressive rise of temperature alters the magnetism of the bar much more when it had been first tempered towards 900° and cooled slowly, than when it had been first put into the annealed state.

When in the annealed state the bar is exposed only to temperatures below 500°, it receives its original force by being again magnetised; but in the state of temper it is not so. Each rise of temperature diminishes perceptibly the magnetic force which the bar can receive from being again magnetised. This is shown in the following table:

Annealing Temperature.	Time of performing Ten Oscillations when again magnetised.
12°	63″
214	64·5
410, colour of water	70
900, cherry red	93

The bar, therefore, attained its maximum energy when tempered at 900°. It then performed ten oscillations in 63″. Setting out from this term, the directive force diminished in proportion as the annealing temperature increased. At 900° the bar, magnetised anew to saturation, employed 93″ to make ten oscillations, as in the first experiments, which ought to have been the case, as it was brought back to the same state of perfect annealing from which it was at first taken.

The bars used by Coulomb were about thirty times as long as they were thick, and with such bars similar results were always obtained. But this was not the case with larger bars. Having taken a steel wire 326 millimetres long and four in diameter, he tempered it at 820°, magnetised it to saturation, and determined its directive force. He repeated the same operation after having annealed it at different temperatures, and the following were the results:

Annealing Temperature.	Time of Ten Oscillations.
12°, temperature of atmosphere	89″
320, colour of water	75
450, deep red	68
530, less deep red	70
900, bright cherry red	76

---

[1] Biot, *Traité de Physique*, tom. iii. p. 106.

Here the hard temper gives the weakest directive force, as we have already seen in the preceding experiments. The maximum effect takes place when the wire is annealed at about 450°, and this result is a general one for all wires and plates whose length is very great relative to their width.

This result seems to be connected with a particular mode of distribution of free magnetism. In bars whose length does not exceed thirty times their diameter, there is never more than one magnetic centre, which is in the middle of the bar. But when the ratio of the length to the breadth is greater than this, magnetising it produces always three centres, one in the middle of the bar, and the other two at equal distances from its extremities. This effect is shown in fig. 30, and in fig. 31. The effect of placing such a magnet in iron filings is shown in fig. 31; and in fig. 30 the curve of the intensities is seen to cross the axis between the centre C and the poles A, B, the two new centres being at C′ and C″.

Fig. 30.

Fig. 31.

M. Coulomb found that the distance C′ A, C″ B of the two new centres from the extremities of the magnet varies with the temper; and the annealing heat is shown by the following results obtained with a wire-magnet 326 millimetres long:—

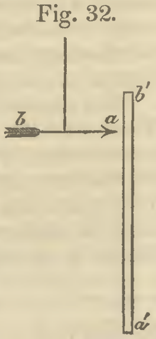
	Time of Ten Oscillations.	Distances of the Centres C′, C″ from the Centre C, the Middle of the Magnet. C′.	C″.
Hard temper	89	98	98
Annealed at the colour of water	75	63	63
Ditto at dark-red heat	68	43	43
Ditto at cherry red	76	0	0

In proportion as the annealing heat increases, the two centres C′, C″ approach each other, and are re-united with the centre C at a cherry-red heat. This last result is very important in the construction of compass-needles. Coulomb regards the *dark red* as the best annealing heat for needles or bars whose length exceeds thirty times their thickness, and the state of hard temper for those where the ratio between the length and the thickness is less.

It is extremely probable, as M. Biot supposes, that when magnets are larger in proportion to their thickness than those used in the preceding experiments, a greater number of centres will be produced, were it from no other cause than the re-action of the plate upon itself.

In examining the influence of temperature on magnets, Professor Kupffer began by examining the effect of heat in altering the distribution of magnetism. For this purpose he took a parallelopiped of tempered steel, 503 millimetres long, 15½ wide, and 5 thick, and having magnetised it to saturation, he heated it, and allowing it to cool slowly, he submitted it to examination. The magnet was placed vertically, as at *a′ b′*, and a needle suspended by a silk fibre was made to oscillate before any point *ab*, in order to determine the intensity of magnetism at that point. In this way he obtained the following results:—

Fig. 32.



Influence of Heat on Magnetism.

M. Kupffer's experimnts.

Distance *ab′* in Millimetres.	Magnet not heated. Magnetic Force.	Same Magnet heated to 80°, and examined after cooling. Magnetic Force.
156	0·5569	0·4376
136·5	0·7374	0·5765
116·5	0·9455	0·7280
96·5	1·1862	0·8897
76·5	1·4311	1·0559
56·5	1·6518	1·1929

Hence it appears that the bar heated to 80° had not only lost much of its magnetic virtue, but that this loss was not uniform along the whole length of the bar, being greater towards the extremities *a′*, *b′* than towards the middle. This may be easily seen by dividing the forces in columns 2 and 3 by one another, when it will appear that the quotients are greater for points nearest *a′* and *b′*.

M. Kupffer next studied the changes which take place in the forces of a magnetic needle when its temperature is increasing, the heat being kept constant during the time of each experiment. He used a cylindrical needle of fused steel, 0·57 millimetre long, and 2·395 grammes in weight. The temperature increased from 8½° to 18°, and the deviation of 300 oscillations varied from 777½ to 781, which shows, as Coulomb had previously observed, that the magnetic force diminished as the temperature increased. By another series of experiments, M. Kupffer has shown, that the diurnal variations of the needle did not at all affect these results.

In order to determine the law of the decrease of the magnetic forces at temperatures above 30°, he made a needle oscillate above a newly magnetised bar 0·5 millimetre long, the opposite poles looking to each other, and he raised the temperature of the bar from 13° to 80°, by means of hot water. At 13°, the needle, when by itself, performed 300 oscillations in 762″, and in presence of the magnet it lost only 429″. When brought to the temperatures in the table, and then cooled, the oscillations of the needle were observed.

Temperature of the Magnet.	Duration of 300 Oscillations.
13°	429
80	476
21	464½
13	463
11	462½

Hence it appears that the magnetic force diminishes with heat, and that a magnet at the temperature of 13°, when heated to 80°, and then cooled to 13°, does not resume its first magnetic state, which is diminished. The cause of this is, that in cooling slowly the bar loses a part of its temper, and consequently a part of its free magnetism.

From these observations M. Kupffer deduces the following formulæ, which represent with great accuracy the influence of temperature, viz.

$$x = \frac{n}{\sqrt{c + \mathrm{F}}}$$

$$x' = \frac{n}{\sqrt{\left(c + \mathrm{F} - \frac{(1-q)^{\mathrm{F}}}{67}\right)(t - 13)}},$$

where c is the force exerted by the earth on the oscillating needle.

x, the number of seconds in which n oscillations are made.

F, the force exerted by the bar at the same temperature.

x', the number of seconds which the same needle employs at the temperature t.

Influence of Heat on Magnetism.

p, the intensity of the magnetic force of the bar at 13°; and

q, the intensity of the same force at 80°.

M. Kupffer proceeded to examine the effects which the heating of only one pole of a magnet produced upon the distribution of its magnetism. With this view he placed a magnet parallel to a needle suspended horizontally, the dissimilar poles being placed opposite to each other. The needle will not remain in the magnetic meridian unless its neutral point and that of the bar are in the same line perpendicular to the needle. This position may be found by a few trials. When by shifting the magnet its neutral point approaches one of the poles of the needle, and always in the same direction, this pole will be repelled, because the opposite pole of the needle is more strongly attracted by the corresponding pole of the magnet, which is brought near it, while the other is removed from it.

Let us now heat the north pole of the magnet; the south pole of the needle opposite to it will be soon attracted. Hence it is clear that the point of indifference, or neutral point, has receded from the heated pole, or from the pole whose magnetic intensity is diminished, which agrees with the law of Coulomb. The following results were obtained with a magnet 0·5 millimetre long, the needle being placed in the magnetic meridian :—

Temperature of the extremity of the Bar.	Duration of 100 Oscillations.
0° Reaumur.	275·5 seconds.
13	276
40	278
56	279·5
15	277·5
11	277

When the magnet had cooled slowly, the needle returned gradually to its first position; but it never recovered it entirely. By the earth's action only, the needle performed 50 oscillations in 207″.

When a bar of soft iron was substituted for the magnet, and placed in the magnetic meridian, it was magnetised by the action of the earth. When one of its extremities was heated, the pole of the needle next it was *attracted* instead of *repelled*, the neutral point having *approached* to the heated extremity, in place of *receding* from it as formerly. Hence the magnetic force of the iron was *increased* by heat.

Mr Christie's experiments.

In examining the diurnal deviations of the needle when under the influence of magnets, Mr Christie conceived that the deviations might be partly the effect of changes in the temperature of the magnets; and he therefore undertook a series of experiments to determine the precise effects of changes of temperature on magnets. By a peculiar apparatus and a method of observation which our limits will not allow us to introduce, he obtained the following results :—

Mean Temperature of the Magnets. Fahr.	Difference of Heats in successive Observations.	Magnetic Intensity.	Variation of Intensity for 1° of Fahr.
62°·05	— 3°·00	212·5620	0°·1268
59 ·05	+ 18 ·60	212·9423	0 ·1247
77 ·65	— 3 ·65	210·6228	0 ·1004
74 ·00	— 3 ·35	210·9892	0 ·1279
70 ·65	— 3 ·50	211·4178	0 ·1193
67 ·15	— 3 ·35	211·8353	0 ·1138
63 ·80	— 1 ·75	212·2167	
62 ·05		212·4640	0 ·1413

By discussing these results, Mr Christie concludes that 0·1226 is the mean variation of the intensity of the magnets, from a change in their temperature of 1° between the temperatures of 59°·05 and 77°·65. Taking the case where the intensity at 60° was 218, the change for 1° was 0·123; and supposing the intensity to be 1, each degree will produce a diminution of 0·000564.

Action of Simple Iron Bodies on the Magnetic Needle.

From a number of experiments made with a balance of torsion, the needle being suspended by a brass wire $\frac{1}{450}$th of an inch in diameter, Mr Christie ascertained the following facts:

1. Beginning with — 3° of Fahrenheit, up to 127°, the intensity of magnets decreased as their temperature increased.

2. With a certain increment of temperature the decrement of intensity is not constant at all temperatures, but increases as the temperature increases.

3. From a temperature of about 80°, the intensity decreases very rapidly as the temperature increases; so that if, up to this temperature, the differences of the decrements are nearly constant, the differences in the decrements also increase.

4. Beyond the temperature of 100° a portion of the power of the magnet is permanently destroyed.

5. On a change of temperature, the most considerable portion of the effect on the intensity of the magnet is produced instantaneously, showing that the magnetic power resides on or very near the surface.

6. The effects produced on soft iron by changes of temperature are directly the reverse of those produced on a magnet; an increase of temperature causing an increase in the magnetic power of the iron. This was observed between the temperatures 50° and 100° Fahr. Mr Christie regards this fact as a strong argument against the hypothesis, that the action of iron upon the needle arises from the polarity which it receives from the earth.[1]

CHAP. VI.—ON THE ACTION OF SIMPLE IRON BODIES ON THE MAGNETIC NEEDLE.

Action of simple iron bodies on the needle.

Mr Barlow undertook the interesting experiments which we are about to describe, with the view of discovering some method of correcting the local attraction of a ship's guns and other iron on the compass-needle.

His attention was first directed to the action of solid spheres and spherical shells of iron; but he afterwards applied the principles to which he was led, to the action of bars and plates of simple iron, and to irregular masses. We shall therefore lay before our readers, in three separate sections, the results of his experiments and theoretical investigations respecting these two forms of unmagnetised iron.

SECT. I.—*On the Action of Spheres and Spherical Shells of Iron on the Magnetic Needle.*

Action of spheres on the needle.

The earliest experiments of Mr Barlow, by which he was led to some of the properties of iron spheres, were made in an imperfect manner; but the phenomena were such as to induce him to construct an apparatus capable of affording him the most accurate measures of the deviation of the needle.

The apparatus which he finally employed is shown in Plate CCCXXV. fig. 6. It consists of a large and steady round table TT, having its surface horizontal. The points of the compass are laid down on its upper face. In its centre is a hole $18\frac{1}{4}$ inches wide, for receiving an eighteen-inch or smaller iron shell or ball B, which is suspended above it by pulleys *pp*, which allow the observer to raise lower it at pleasure. When a diameter of this table is ought into the magnetic meridian, Mr Barlow found, at in whatever part of the table a compass-needle was aced, except in the meridian, the *south* end of the needle as drawn to the ball when the latter was wholly above e table, as in the figure. The attraction increases as e ball descends, till at a certain point it is a maximum, d then decreases again towards zero as the ball de- ends farther. Hence it is clear, that there is all round e ball a position where the attraction is zero; and it was sily observed that these points lay in a plane inclined to e horizon. In this way Mr Barlow established his fun- amental principle, that

---

[1] See *Philosophical Transactions*, 1825, p. 1–65.

In every ball or shell of plain unmagnetised iron there ists a plane of no attraction, or a plane in which the iron oduces no disturbance on the needle, and which plane in- ines from north to south (magnetic), forming with the ho- zon an angle equal to the complement of the dip.

This line on the surface of the ball may be called the agnetic equator; and, taking the meridian which passes rough the east and west points as the first, Mr Barlow able to designate every part of his iron sphere by the agnetic longitude and latitude of that point.

Mr Barlow therefore proceeded to determine whether e quantity and deviation at any point could be expressed any function of the latitude and longitude of that point, en the mass of the ball and the distance of the needle m it were constant. From these experiments, which it unnecessary to detail, he found,

That the tangent of the deviation of the needle is propor- nal to the rectangle of the sine and cosine of the latitude, to the sine of the double latitude.

By observing the deviations throughout a great circle in ich the longitude was constant, and also in a circle in ich the latitude and longitude were variable, he found e following law,—

That the tangent of the deviation of the needle is nearly oportional to the sine of the double latitude multiplied by e cosine of the longitude.

By comparing the constant numbers obtained on the eceding principles at different distances *from the centre the sphere*, Mr Barlow found,

That the tangent of the deviation is inversely proportional the cube of the distance.

The remaining object of Mr Barlow's inquiry was a very eresting one, namely, to determine the law of the de- tion as dependent on the mass of the iron ball by the tion of which it was produced. The result was equally w and unexpected. He found,

That the tangent of the deviation was directly proportional the cube of the diameter of the ball or shell; but that it is ll wholly independent of the mass, being the same in quan- y whatever be the thickness of the metal, provided only t it exceed one twentieth of an inch.

Hence it follows, *that the entire magnetic power of an n sphere resides on the surface, and is independent of the idity.*

Mr Barlow was so much surprised at this result, that constructed a ten-inch shell of tin plate and another iron plate, the former weighing forty-three ounces and e latter forty-five ounces, and he found that the power neither was so great as that of the solid ball of the same meter, but approached to it in the ratio of two to three. the thickness of the iron in these shells was at an ave- ge about one thirtieth of an inch, Mr Barlow concluded at the magnetic fluid requires a certain thickness of tal, exceeding one thirtieth of an inch, in order effec- lly to develope itself, and act with its maximum energy.

This important result was some time afterwards veri- d by Captain Kater, with three cylinders, one of soft n, and one tenth of an inch thick; another of what is called chest-plate, 0·185 of an inch thick; and the third solid. The deviations produced by these three cylinders, when reduced to the same extent of surface, were 141, 184, and 187, thus proving that the cylinder whose thickness was only 0·185, or between one fifth and one sixth of an inch thick, had the same magnetic power as a solid cylinder of iron. The distribution of magnetism on the surface of magnetic bodies presents us with another interesting analogy between the magnetic and electric fluids; and it deserves our particular notice, that in the results obtained by Mr Barlow, the action of the sphere is related to the centre of its mass, and not to the poles of its magnetic equator.

Action of Simple Iron Bodies on the Magnetic Needle.

Professor Barlow on the action of iron spheres.

Mr Barlow next proceeds to the investigation of analytical formulæ which shall exhibit the action of iron spheres upon a magnetic needle. In this inquiry he sets out with the established experimental fact already mentioned, *that the entire magnetic power of an iron sphere resides on the surface, and is independent of the solidity;* and he proceeds on the following hypothesis.

1. Magnetic phenomena are due to the existence of two fluids in a greater or less degree of combination, and such that the particles of the same fluid repel, and those of an opposite nature attract, each other.

2. These fluids in iron bodies exist naturally in a state of combination and equilibrium till that state is disturbed by some exciting cause.

3. But if a body already magnetic, *i. e.* one in which the fluids are held in a state of separation, be brought within the vicinity of a mass of iron, such as is supposed above, the concentrated action of each fluid in the magnetised body will act upon the latent fluids in the quiescent body, by repelling those of the same, and attracting those of the contrary kind, and thus impress upon the latter a temporary state of magnetic action, which will remain only while the two bodies maintain their respective situations.

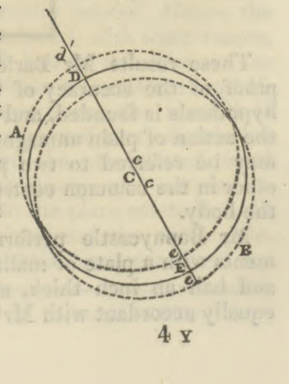
4. The quantity of action impressed upon the iron body will depend, 1*st*, upon the intensity of the exciting magnet; 2*dly*, upon the capacity of the quiescent body for magnetism, or the quantity of those fluids contained in it; and, 3*dly*, upon the cohesive power of the iron; which latter quality determines the depth to which the exciting magnet is able to disengage the two fluids.

The above embraces every case, namely, of any magnet, natural or artificial, developing the magnetism in any given iron body; but the displacement occasioned by the magnetic action of the earth, or spheres of iron, is more limited in its results, and more susceptible of correct mathematical investigation.

5. In this case, for instance, we may suppose the action to take place on every particle of the mass in lines parallel to each other, and corresponding in direction with the dipping needle; also, that every particle is at the same distance from the centre of the disturbing force, and consequently that the displacement in each particle is equal also.

6. For the sake of illustration, let ABED represent a sphere of iron in its non-magnetic or quiescent state, and let CM be the line on which the terrestrial magnetism is exerted from a centre of action M, which is at such a distance that the diameter of the sphere is inconsiderable in comparison with it; then every particle on its surface, and to a certain distance within it, will be acted upon by equal powers, and in directions parallel to each other, whereby the fluids

Fig. 33.



Action of Simple Iron Bodies on the Magnetic Needle.

in the quiescent body, before in a state of combination, will be separated in each particle; and the two fluids may now therefore be conceived to form two spherical shells AeBd, Ae′Bd′, whose centres of action will be c, c', their distances from each other being greater or less, according to the circumstances stated in No. 4.

Professor Barlow on the action of iron spheres.

7. Therefore, in computing the action of such a mass of iron, in its temporary state of magnetism, upon a distant particle of magnetic fluid, Mr Barlow refers it to these centres, and assumes that the law of action in this, as in other cases of emanating forces, is inversely as the squares of the distance.

By means of this hypothesis Mr Barlow arrives at the following formula for the deviation Δ of a horizontal needle.

$$\text{Tan. } 7\,\Delta = \frac{C}{M}\cdot\frac{3r^2}{2d^3 \cos.\,\delta}\,(2\lambda\cdot\cos.\,l),$$

where $r =$ radius of the iron spheres;

$d =$ the distance of the needle from the centre of the spheres;

$\lambda =$ the complement of the magnetic latitude;

$l =$ the complement of the magnetic longitude;

$\delta =$ the dip of the needle; and

$\frac{C}{M} = 1{\cdot}0539$ a constant quantity for cast-iron balls and shells, of every diameter, and for all distances and positions.

From this formula it necessarily follows,—

1. That though the development of the magnetism of the spheres takes place by the hypothesis only at the surface, yet the effect, as shown by the tangent of the deviation, is proportional to the cube of the diameter.

2. That the tangent of deviation is inversely as the cube of the distance.

3. That the tangent of the deviation is proportional to the sine of the double latitude and cosine of the longitude, the latter being extended from the east and west points.

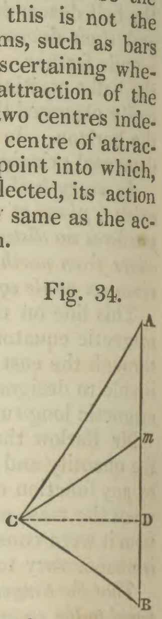
These are the very laws which Mr Barlow had deduced from experiment, and he has established the correctness of his formula by comparing it with a great body of experiments made by himself and Mr Christie, and also with observations on the dipping needle.

SECT. II.—*On the Action of Simple Iron Bars and Plates on the Magnetic Needle.*

Action of Simple Iron Bodies on the Magnetic Needle.

As spherical bodies possess the peculiar property of having their centre of attraction in the centre of the mass, the former becomes a fixed point, whatever be the distance of the magnetic needle. As this is not the case, however, with bodies of other forms, such as bars and plates, Mr Barlow was desirous of ascertaining whether, in these cases also, the magnetic attraction of the body could be referred to the action of two centres indefinitely near to each other in the general centre of attraction of the surface of the body, viz. that point into which, if all the matter of the surface were collected, its action on the centre of the needle would be the same as the action of the whole body in its natural form.

Fig. 34.



In pursuance of this plan, he supposes AB to be a bar of iron, and C the place of the needle, and, letting CD fall perpendicular on AB, he joins AC, mC, BC. He then finds the following expression for the deviation, $\tan.\,\Delta = A\,\frac{mn \cos.\,l}{(m^2+n^2)^{\frac{1}{4}}}$, A being a constant quantity, l the longitude, m the force in the direction DC, and n the force in DA. In the experiments with which Mr Barlow proposed to compare this formula, the needle was placed due east and west of the bar, the longitude of its position was zero, and hence $\cos.\,l = 1$. The formula, therefore, becomes

$$\tan.\,\Delta = A\,\frac{mn}{(m^2+n^2)^{\frac{1}{4}}} \text{ or } \tan.\,\Delta\cdot\frac{(m^2+n^2)^{\frac{1}{4}}}{mn} = A,$$

whatever may be the distance of the needle or its position, provided its longitude be zero. The following experiments were made by Mr Charles Bonnycastle, with a bar twenty-four inches long and an inch and a quarter square, inclined in the direction of the dipping needle. The magnetic needle was placed to the east and west of the bar, first opposite to its centre m, and then at every three inches from the centre to the extremities, at the distance of twelve and sixteen inches from the axis of the bar. The following were the results.

Mr Bonnycastle's experiments.

Distance of Compass from Bar in inches.	Distance below Centre.	Observed Deviation.	Value of $\frac{mn}{(m^2+n^2)\frac{1}{4}}$	Values of A.
16	3	2° 20′	·00240	17·03
16	6	4 25	·00438	17·62
16	9	5 45	·00563	17·88
16	12	6 0	·00596	17·63
12	3	5 20	·00484	19·28
12	6	10 0	·00899	19·62
12	9	12 0	·01152	18·45
12	12	11 30	·01160	17·54
				Mean....18·13

These results Mr Barlow justly regards as a further proof of the accuracy of the principles upon which his hypothesis is founded, and of his general deduction that the action of plain unmagnetised iron on a compass needle may be referred to two poles indefinitely near to each other in the common centre of attraction of the surface of the body.

Mr Bonnycastle performed another series of experiments with a plate of malleable iron twelve inches square and half an inch thick, and he obtained results almost equally accordant with Mr Barlow's hypothesis.

SECT. III.—*On the Action of Irregular Masses of Iron on the Magnetic Needle.*

Action of irregular masses of iron.

Mr Barlow was next desirous of ascertaining if the same law which applied to spheres, bars, and plates, was true in irregular masses of iron, such as a 24-pounder gun; an experiment peculiarly applicable to the object he had in view. He found that the plane of no attraction existed in the most irregular masses of iron, and the agreement between the observed deviations produced by the gun, and those calculated by his formula, was such as to satisfy him that the same laws applied to irregular as to regular masses of iron; and he was thus furnished with the means of computing the local attraction of a ship's guns upon the compass under all circumstances, and in all parts of the world.

These views have been strikingly confirmed by several ingenious observations, made, without knowing of Mr Barlow's labours, by Mr Lecount of the navy, with bars, handspikes, mast rings, and various other iron bodies, from which he concluded "that a plane or circle held east and west (magnetic), and at right angles to the direction of the dipping needle, divides the north from the south magnetic effluvia, each lying on that side to which the dipping needle points; and by referring the position of all iron bodies to this plane, the plane of section shall divide the two into north and south polarity, provided it be of uniform thickness, or, if not, the section must be drawn through its centre of (gravity) attraction."[1]

CHAP. VII.—ON THE INFLUENCE OF MAGNETISM ON CHEMICAL ACTION.

Influence of Magnetism on Chemical Action.

An opinion had long prevailed among philosophers that the phenomena of magnetism and electricity had a similar origin; and hence various observers had been led, previous to the discovery of electro-magnetism by Oersted, to inquire if any actions of a chemical nature could be produced by magnetism.

The German philosopher Ritter was the earliest and the most active of these inquirers. He maintained that a magnetic wire, combined with another wire not magnetised, produced contractions in a frog, the south pole of the wire-magnet producing stronger contractions than the unmagnetised wire; and as he had constantly observed that the metals most susceptible of excitation excited the strongest contractions, he concluded that the south pole of a magnet has a greater affinity for oxygen than simple iron, and the north pole a less affinity. Hence he was led to confirm these views by means of several chemical reagents. He placed a magnetised wire upon pieces of glass in an earthenware dish containing weak nitric acid, when he found that the south pole was more corroded by the acid than the other, and was soon encircled with a deposition of oxygen greater than that at the other pole. In another experiment he took two flasks filled with tincture of turnsol, in one of which he placed the two south poles of two wire-magnets, and in the other the north poles of two similar magnets. In the last flask the oxidation of the wires was much greater than in the first.

The difference in the oxidation of the south pole was exhibited by Ritter in another way. He took three small and equal bottles filled either with pure or slightly acidulated water, and having placed in one the south pole of a wire-magnet, in another the north pole, and in the third the extremity of an unmagnetised wire of the same length, he observed that the south pole first began to deposit oxide, the unmagnetised wire next, and the north pole last. In order to exclude the access of air, the surface of the water should be covered with very fresh oil of almonds; and as light accelerates oxidation, none of the bottles should be more exposed to the sun than the rest. In support of this last observation, Ritter exposed two iron wires to the sun when placed in water, and having covered one of the bottles with black paper, he found that the wire in the uncovered bottle was oxidated more rapidly than the other. Ritter repeated the preceding experiment with the three bottles containing an infusion of litmus in place of acidulated water. The south pole reddened the infusion most, the unmagnetic wire less, and the north pole least of all. A week is required to produce a distinct effect; and in order even to effect this, Ritter found it necessary to add as much acetic acid as would incline the infusion to red without completely changing its colour.

Experiments of Ritter.

The following experiment of Ritter, if correctly repeated, establishes the same result. We shall give it nearly in his own words: "Sixteen magnetic wires, of equal size and power, were placed in six vessels, all equally full of a mixture of one part nitric acid and thirty-six parts water, in the following manner: In the first glass were placed two wires, one with the north pole immersed in the fluid, the other with the south, and not more than half a line asunder; in the second, the same, but the wires an inch and three fourths apart; in the third and fourth were each three wires, with the south poles of all immersed, but their distances in the two glasses different, as in the first and second; in the fifth and sixth were wires similarly arranged, but with the north poles immersed. Different quantities of oxide were gradually deposited, and, to express the whole in a few words, we will call the south pole S, the north pole N, their greater distance g, and their less p, and we will express the order of oxidations as follows: $\mathrm{SN}g > \mathrm{SN}p > 3\mathrm{S}p > 3\mathrm{S}g > 3\mathrm{N}p > 3\mathrm{N}g$. On the nineteenth day it was observed that the loss of fluid by evaporation had not been equal in all the vessels, but took place in the inverse order of the oxidations. All the magnetic wires were weakened in power; $\mathrm{NS}g$ least, $\mathrm{NS}p$ more; of the wires $3\mathrm{S}p$, two had lost less power than the third; and in like manner $3\mathrm{S}g$, $3\mathrm{N}p$, $3\mathrm{N}g$, had each two left more powerful than the third; the strongest were equal to $\mathrm{NS}g$."

Experiments of Muschman,

The next experiments on this subject were made by M. Muschman, professor of chemistry in the university of Christiania, who endeavoured to ascertain the effect of the earth's magnetism on the precipitation of silver. In his chemical course in 1817, when he was desirous of explaining the chemical theory of the tree of Diana, he took a tube like a syphon, and poured mercury into it, which accordingly occupied the lower part of the two branches: above the mercury he poured a strong solution of nitrate of silver. He then placed the two branches of the syphon so that the plane passing through them was in the magnetic meridian, and after standing a few seconds, the silver began to precipitate itself with its natural lustre; but it accumulated itself particularly in the northern branch of the syphon, while that which was less copiously precipitated in the other branch had a less brilliant lustre, and was mixed with the mercurial salt deposited from the solution. M. Muschman and Professor Hansteen repeated this experiment in an improved form with the very same result. On this occasion they used simultaneously two syphons prepared in the same manner, the one being placed in the direction of *north* and *south*, and the other in that of *east* and *west*. The silver began to precipitate itself in the direction of *north* and *south*, and it particularly raised itself in the *north* branch with a lustre more brilliant than in the *south* one; whereas in the syphon whose plane lay *east* and *west*, *no change had taken place even at the end of twelve hours.* Hence the two Norwegian philosophers concluded, with some reason, that the magnetism of the earth had an influence on the precipitation of silver from a solution of its nitrate; and M. Muschman inferred, from the experiment, the identity of galvanism and magnetism. He regarded every dissolution as the result of a galvanic effect, the precipitated metal carrying off the electricity set at liberty, and carrying itself, in order to be disengaged, to the place where it could find the opposite electricity, which was the north pole. M. Muschman considered this hypothesis confirmed by

and Hansteen.

---

[1] Lecount *on the Magnetic Properties of Iron Bodies.*

the geological fact, that at Königsberg silver was found in the metallic form, stretching from north to south; and the presence of the silver is always indicated by a certain quantity of pyrites and blendes. Hence he conceived that the silver had been insensibly united to sulphur, and that by the effect of the earth's magnetism alone it had been carried towards the copper and the zinc.

Experiments of Fresnel;

M. Fresnel made a series of experiments with the view of decomposing water by the magnet. He proposed to produce an electric current in an electro-magnetic helix enclosing a bar-magnet covered with silk. The two ends of the wire were plunged in slightly acidulated water, and he observed very decided effects; but there were so many anomalies in the result, which he could not explain, that he abandoned the inquiry. He was particularly struck with the fact, that the wire which should be the positive one was strongly oxidated, whilst the other extremity preserved its metallic lustre during a whole week. The negative extremity was covered with a saline deposite, which he conjectured to be sulphate of lime, and which he supposed had protected the wire from oxidation.

of Erdman.

M. Erdman, after a very elaborate inquiry into the effects of magnets as chemical agents, came to the conclusion that the observed phenomena were due to the influence of other causes, which had not been sufficiently guarded against.

A curious fact, connected perhaps with the class of phenomena under our observation, was noticed by M. Lebaillif. He observed that the poles of a magnetic needle delicately suspended were repelled by pieces of antimony or bismuth that were brought near them.

CHAP. VIII.—ON THE LAWS OF THE MAGNETIC FORCES, THE MUTUAL ACTION OF MAGNETS, AND MAGNETIC CURVES.

SECT. I.—*On the Law of the Magnetic Force.*

Law of the magnetic force.

In our history of magnetism we have given very full details of the various attempts which were made by philosophers to determine the law according to which the intensity of the attractive and repulsive power of magnets varied with the distance at which these forces were exerted. Like all other laws, an approach to the discovery of it had been made by various philosophers; but the merit of its perfect establishment undoubtedly belongs to Dr Robison and Coulomb, the last of whom placed it beyond the reach of doubt. The difficulties which were to be overcome in this inquiry arose from the invariable co-existence of two opposite polarities in each of the two bodies whose mutual action was under examination; and this difficulty was increased from these polarities not being concentrated in particular points, but diffused in an unequal degree over each half of the magnet and the needle.

Researches of Coulomb.

In this delicate inquiry Coulomb employed two methods. In the first he suspended a magnetic needle by a silk fibre, and when it was in the magnetic meridian, he presented to it at different distances another magnetic needle, and determined by observation and calculation the force with which they acted upon each other at these distances. A needle an inch long, weighing seventy grains, and magnetised to saturation, was suspended by a fibre of silk three lines long, and a steel wire magnet twenty-five inches long was placed vertically in the magnetic meridian at different distances, so that its south pole was always ten lines below the northern extremity of the suspended needle. The needle was now made to oscillate when the magnet was at different distances from it, and the following were the number of oscillations in 60″, the number being fifteen when the magnet was removed, and the needle influenced only by the magnetism of the earth.

Distance of a Wire Magnet from the middle of the Needle.	Number of Oscillations in 60″.
4 inches	41
8 ditto	24
16 ditto	17

By means of the formula for the pendulum, in which the forces are in the direct ratio of the square of the number of oscillations performed in the same time, Coulomb has computed their intensity. As all the forces concerned are in the plane of the magnetic meridian, the force which produces the horizontal oscillations depends on the parts of these forces which are decomposed in a horizontal direction. Now Coulomb had demonstrated that the magnetic fluid might be considered as concentrated at a point ten lines from the extremity of the wire-magnet; but as the suspended needle was one inch long, its north pole was attracted at the distance of three and a half inches, and its south pole at the distance of four and a half inches, so that four inches was the mean distance at which, in the first experiment, the lower pole of the wire-magnet exerted its action on the two poles of the needle. In the second experiment the mean distance was eight inches. But as the horizontal force which produces the oscillations is the square of the number performed in 60″, the magnetic force of the earth will be 15^2, and the combined forces of the earth and the wire-magnet will, in the first, second, and third experiments, be 41^2, 24^2, and 17^2, so that the forces which emanate from the wire-magnet will be $41^2 - 15^2$, $24^2 - 15^2$, $17^2 - 15^2$, whence we deduce the following results:

	Mean Distance.	Force depending on the Action of the Wire-magnet.
1*st* experiment	4 inches	$41^2 - 15^2 = 1456$
2*d* experiment	8 ditto	$24^2 - 15^2 = 351$
3*d* experiment	16 ditto	$17^2 - 15^2 = 64$

The distances in the first and second experiments being as one to two, the variation of the force would have been exactly as the squares of these numbers had the force in the second experiment been 364 instead of 351; and the same would have been the case had the force in the second and third experiments been 332 and 83, instead of 351 and 64. This difference, therefore, requires to be investigated. Coulomb has accounted for it, and calculated the correction for these numbers in the following manner. In the experiments the action of the superior pole of the wire-magnet was neglected. The distance of its inferior pole from the centre of the needle was sixteen inches, and the distance of the superior pole from the centre of the needle is nearly $\sqrt{(16^2 + 23^2)}$, so that the force of the former is to that of the latter nearly as 100 to 19. Hence, as the oscillations of the needle are produced by the action of these two poles, which exert their force in opposite directions, the square of the number of oscillations which the single action of the inferior pole of the magnet would produce should be diminished $\frac{19}{100}$ths by the opposite action of the superior pole; so that 64 is only the excess of the real amount of the single action of the lower part of the magnet over $\frac{19}{100}$ths of the number which represents it. The true value will therefore be 79. The true intensities of the forces will, at the distances 4, 8, and 16 inches, be 1456, 351, and 79, or nearly in the inverse ratio of the squares of the distances.

M. Coulomb has in like manner demonstrated, that the repulsive force of similar poles follows the same law of the distance.

Coulomb magnetic balance.

The *second* method employed by Coulomb requires the use of the magnetic balance, which is represented in Plate CCCXXV. figs. 1 and 5, which is a modification of the torsion balance already described in our article on ELECTRICITY. The suspending wire, *ab* fig. 1, carries at its lower extremity a pair of pincers *c*, which holds a stirrup

1, 2, 3, formed of a plate of very light copper. In this stirrup is placed a small piece of card covered with a coat of Spanish wax, on which is impressed the mark of the wire or bar of steel SN to be used, in order that it may always be put in the same position. Under the middle of the stirrup is fixed a vertical plane PP, wholly immersed in a vessel VV of water, the resistance of which may quickly stop the oscillations of the needle or magnet SN in the stirrup. When fitted up for the experiments under our consideration, the apparatus shown in fig. 1 is placed in a square box AB (see fig. 5), three feet wide and eighteen inches high. At the height of nine inches above the bottom is placed a horizontal circle of wood or copper, two feet ten inches in diameter, and divided into degrees. On this box is placed a cross piece CD, which supports at its middle point a tube EF, thirty inches long, and terminating in a torsion micrometer at M. The pincer of this micrometer holds the upper end of a brass wire, to the other extremity of which is adapted a ring of copper intended to carry a steel needle.

Before the commencement of the experiment, the box AB is placed so that the direction of the magnetic meridian passes through the divisions *zero* and 18° of the horizontal circle. The next step is to place in the stirrup a well-magnetised steel needle NS, of a rectangular form, and to adjust the torsion micrometer M, so that the torsion of the wire is nothing when the needle NS is in the magnetic meridian, or that the magnetic meridian passes through the *zero* on the scale of the torsion micrometer. In the direction of the magnetic meridian, a vertical ruler of wood or copper, one or two lines thick, is fixed, so that the end of the needle may come against it when it is in the magnetic meridian.

Coulomb now took two wire-magnets, twenty-four inches long and one and a half inch in diameter, and he placed one of them in the stirrup, as at NS, and he determined the force with which the magnetism of the earth drew it back into the magnetic meridian. For this purpose he twisted the suspending wire *ab* through two circles or circumferences minus 20°, till the needle stopped 20° from the magnetic meridian, so that, considering the forces as nearly proportional to the arcs (when the angle is about 20°), about 35° of torsion were necessary to keep the magnetic needle one degree out of the magnetic meridian. The two circles of torsion *minus* 20° are equal to $2 \times 360° - 20° = 700°$; the degrees of torsion required to keep the needle 20° out of the magnetic meridian, or 700° of torsion, are a measure of the directive force of the needle when 20° out of the magnetic meridian. For any other number of degrees, δ, the degree of torsion necessary to balance the directive force will be $700 \dfrac{\sin. \delta}{\sin. 2°}$, because the directive forces are proportional to the sines of the angles. But at 20° the angles may be substituted for the forces, and we shall have $\dfrac{700\,\delta}{20} = 35\delta$, that is, as we stated above, 35° of torsion will balance the directive force of the needle when one degree out of the magnetic meridian. Coulomb now placed the other similarly magnetised wire vertically in the magnetic meridian, so that if the two wires had been prolonged, they would have met at the distance of *ten* lines from their extremities, the point where the magnetism of each acts as if it were concentrated there. He placed the similar poles of each opposite to each other, and consequently the horizontal needle or wire was repelled out of the magnetic meridian; and it took a position at which the force of repulsion of the vertical needle or wire was balanced by the united forces of torsion and the earth's magnetism, which tended to bring the horizontal wire to rest. The following results were obtained after different trials:

Circles of Torsion given to the Suspending Wire by the Torsion Micrometer.	Observed Angles of Repulsion.
0	24
3	17
8	12

Now, in the first experiment, the angle through which the horizontal wire was repelled was 24°, reckoning from the zero of torsion; and when it rested in this position, it was driven towards the zero by a force of torsion of 24° *plus* the directive force of the earth's magnetism, which being 35° for every 1°, amounts to $24 \times 35° = 840°$. The total repulsive force was therefore $840° + 24° = 864°$.

In the second experiment the torsion micrometer was turned round *three* circles in a direction opposite to the 24° first produced; but notwithstanding this great torsion, the horizontal wire-magnet, repelled by the vertical one, returned only to 17° from the magnetic meridian. The force of torsion was therefore 3 circles $+ 17° = 1097°$; but the directive force for 17° is $17° \times 35° = 595°$, hence we have for the total repulsive force $1097° + 595° = 1692°$.

In the third experiment the torsion micrometer was turned round eight circles, and the wire-magnet stopped at 12° from the magnetic meridian. The force of torsion was therefore 8 circles $+ 12° = 2892°$; but the directive force for 12° is $12° \times 35° = 420$, hence we have for the total repulsive force $2892° + 420 = 3312°$.

As the arcs of repulsion are in these experiments so small, we may safely reckon them equal to their chords, and we obtain the following results:

Distances at which the Repulsive Force is exerted.	Corresponding Repulsive Forces in Degrees of Torsion.
12	3312°
17	1692
24	864

Assuming 3312° as correct, the other numbers ought to have been 1650 and 828 instead of 1692 and 864, if the force varies inversely as the square of the distance. The differences 42° and 36° correspond nearly with a degree of error in the observed position of the moveable steel wire, since the directive force is 35° for every degree of deviation from the magnetic meridian. Such an error is certainly a very small one in experiments of this kind, and we therefore conclude that the attractive and repulsive forces of magnets decrease as the squares of their distances increase.

Had the experiments been made upon magnetic points, such an error would not have existed; but they were made with forces diffused over portions of the wire-magnet of some extent. In the last experiment (M. Biot remarks) "when the two wires were nearest each other, the influence of the points lying near the intersection was more weakened by obliquity than in the other experiment; or, in other words, there were at equal obliquities more points which acted in the greater distances (24 and 17) than in the smaller one (12). But as we did not take this augmentation into account, we ought to find that the repulsive force observed at the smaller distance, being reduced in the ratio of the square of the distance, gives for larger distances repulsive forces a little more feeble than those which were actually observed.

In the first method of observation, Coulomb was obliged to calculate the effect of the distant pole; but in the present method this was unnecessary, as the wire-magnets were two feet long, and the greatest arc of repulsion, viz. 24°, corresponded to a distance of five inches between the repelling poles. The other poles were therefore at least four times more distant than those whose repulsive action was calculated; their direct action was therefore sixteen times weaker, besides being greatly weakened by the extreme obliquity with which it acted. Had the wire-magnets been shorter, the action of all the poles might have been taken into consideration.

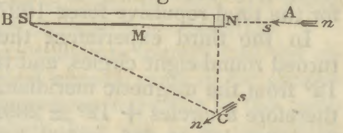
Sect. II.—*On the Mutual Action of Magnets.*

Mutual action of magnets.

We have already seen, from Professor Barlow's experiments on spheres and bars of soft iron, that they act upon needles, whether temporarily or permanently magnetised, as if their magnetism emanated from the centre of their surface, or from two points indefinitely near to each other. This, however, is not the case with permanent magnets, in which the magnetic force is concentrated in poles considerably distant from each other.

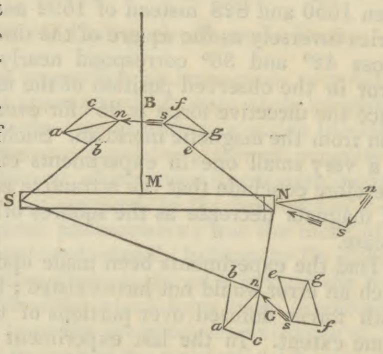
Case 1. When the needle or a small magnet is placed in the line joining the poles of the other magnet.—In considering the mutual action of magnets, we shall suppose the larger one NS to be fixed, and the smaller one *ns* to have the form of a needle, moveable in a horizontal plane round the pivot in its centre A, B, or C. Let the needle then be placed at A, with its centre A in the line S N prolonged, and let us suppose that the magnetic forces emanate from points N, S; *n*, *s*, being the analogous poles of the needle. The north pole N of the magnet *attracts* the *south* pole *s* of the needle with a force inversely proportional to the square of N *s*, and *repels* the *north* pole *n* with a force inversely proportional to the square of N *n*. The effect of both of these forces is to bring *s* as near as possible to N, and to remove *n* as far as possible, that is, to place the needle in the same straight line as N, S, as shown in fig. 35.

Fig. 35.



Case 2. Let the needle, *ns*, be now placed at B, so that its centre B is anywhere in the direction of a right line, MB, perpendicular to the middle M of the magnet. When the centre of the needle is placed above M, it is quite clear that it will stand with its north pole *n* towards the south pole S of the magnet, and its south pole *s* towards the north pole N. When the needle is removed to B, the same thing will happen; S will attract *n* with a force equal to *nb*, while N repels *n* with a force *nc*, a little less than *nb*, on account of the increase of distance. The result of these will be the force *na*, in the diagonal of the parallelogram *ncab*. In the same manner, the pole N will attract *s* with a force *es*, and the pole S will repel *s* with a less force *fs*, the resultant of which is *sg*; but as the poles S, N, are equally strong, and act at equal distances upon the needle, the resulting force *an* must be equal to *gs*, and the needle will remain in that position, which is parallel to the axis SN of the magnet.

Fig. 36.

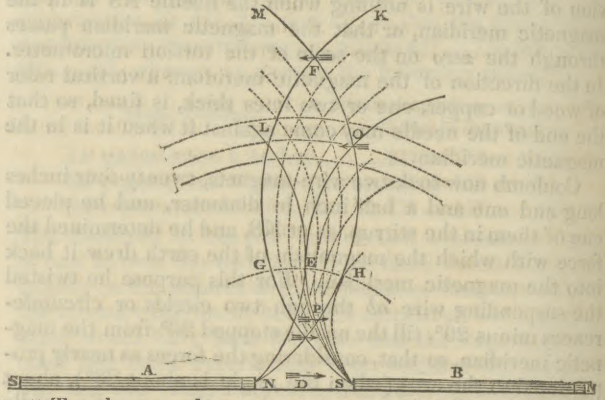


Case 3. When the centre of the needle is placed in an intermediate position, as at C, fig. 36, neither in the axis NS, nor in the perpendicular MB, it will take an intermediate position, which may be thus found. Its north pole *n* is shown in the figure as directed to the centre M of the magnet; but it cannot remain in this position; N repels *n* with a force equal to *nc*, and S attracts it with a force *nb* smaller than *nc*, from the greater distance. The resultant of these is *na*, which is very different from *ns*. For the same reason, the south pole *s*, repelled by S with a force *sf*, and attracted by N with a force *se*, will have a tendency to move in the direction *sg*, nearly equal and opposite to each other; it will therefore take a position *ns*, fig. 36, nearly at right angles to its former position. It will rest therefore in its new position, with its north pole towards N, and its south pole towards S.

If we project upon paper the magnet and the needle placed in different positions, and make the forces of each pole of the magnet on each pole of the needle inversely proportional to the squares of the distances, it will be easy to find the position in which the needle will rest at any distance from the magnet, and at any position of its centre, with regard to the axis of the magnet.

When a needle is exposed to the combined action of two magnets, as shown in the annexed figure, the phenomena, though capable of calculation by the principles already explained, are extremely perplexing and complicated when studied experimentally. Dr Robison, who first discovered and explained these phenomena, has given such an interesting account of them, that we shall make use of his description of the phenomena, leaving the explanation of them to the next section on magnetic curves.

Fig. 37.



“ Two large and strong magnets A and B were placed with their dissimilar poles fronting each other, and about three inches a part. A small needle, supported on a point, was placed between them at D, and it arranged itself in the same manner as the great magnets. Happening to set it off to a good distance on the table, as at F, he was surprised to see it immediately turn round on its pivot, and arrange itself nearly in the opposite direction. Bringing it back to D, restored it to its former position. Carrying it gradually out along DF, perpendicular to NS, he observed it to become sensibly more feeble, vibrating more slowly; and when in a certain point E, it had no polarity whatever towards A and B, but retained any position that was given it. Carrying it farther out, it again acquired polarity to A and B, but in the opposite direction; for it now arranged itself in a position that was parallel to NS, but its north pole was next to N, and its south pole to S.

“This singular appearance naturally excited his attention. The line on which the magnets A and B were placed had been marked on the table, as also the line DF, perpendicular to the former. The point E was now marked as an important one. The experiments were interrupted by a friend coming in, to whom such things were no entertainment. Next day, wishing to repeat them to some friends, the magnets A and B were again laid on the line on which they had been placed the day before, and the needle was placed at E, expecting it to be neutral. But it was found to have a considerable verticity, turning its north pole towards the magnet B; and it required to be taken farther out towards F before it became neutral. While standing there, something chanced to joggle the magnets A and B, and they instantly rushed together. At the same instant the little magnet or needle turned itself briskly, and arranged itself, as it had done the day before, at F, quivering very briskly, and thus showing great verticity. This naturally surprised the beholders; and he now found, that by gradually withdrawing the magnets A and B from each other, the needle became weaker, then became neutral, and then turned round on its pivot, and took the contrary position. It was very amusing to observe how the simply separating the magnets A and B, or bringing them together, made the needle assume such a variety of positions, and degrees of vivacity in each.

"The needle was now put in various situations in respect to the two great magnets; namely, off at a side, and not in the perpendicular DF. In these situations it took an inconceivable variety of positions, which could not be reduced to any rule; and in most of them it required only a motion of one of the great magnets for an inch or two, to make the needle turn briskly round on its pivot, and assume a position nearly opposite to what it had before."

In the preceding observations, the action of the one magnet tended only to change the direction of the other, and this change is clearly produced by the sum of the actions of the two poles of the magnet; for while the one pole tends to draw the one half of the needle into its position of equilibrium, the other pole repels the other half into the same position. The force, therefore, which thus acts upon a needle, is called the *directive force* of a magnet.

The *attractive force* of a magnet is, on the other hand, equal to the difference of the two forces exerted by its poles on the needle; and when the two forces happen to be equal, the attractive force will be nothing, and the needle will have no tendency to approach the magnet, though the directive power of the latter may be very great. This will be understood from fig. 36, when the needle *ns* is at right angles to the axis of the magnet. The attraction of the pole N for *s* is equal to its repulsion of *n*, and these two forces will neutralise each other, so as to prevent any tendency to approach N, even if the needle *ns* were free to do it. On the other hand, in fig. 35, where the needle at C has its south pole *s* more attracted by N than its north pole *n* is repelled by it, the predominance of the attraction would carry the needle towards N if it were at liberty. These views explain the well-known fact, that a needle floated on a piece of cork quickly places itself in the magnetic meridian; but it never will approach the north side of the vessel. In order to explain this fact, Dr Gilbert asserted, that the directive power of a magnet extended much farther than its attractive power; a mistake which arose from his not having observed the effects of the simultaneous action of the four poles of the magnets which acted upon each other.

SECT. III.—*On Magnetic Curves.*

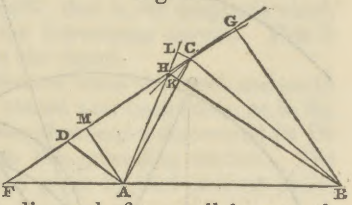
The name of magnetic curves has been given to those curves into which an infinite number of very minute needles would arrange themselves when placed round a magnet, and at liberty to move round an axis. A rude idea of these curves is given by the appearance of iron filings when scattered upon a sheet of paper, and agitated immediately above a magnet.

The action of a magnet upon a needle is greatly simplified when the needle is so small that its two poles may be considered as coincident; in which case the difference between the action of any one pole of a magnet upon them will be infinitely small. When this is the case, the directive force of the magnet upon the small needle must be very considerable, while the attractive force, measured by the difference of the action on the two poles, is nothing. Hence it is that alone which is concerned in the arrangement of minute needles or particles subjected to the action of a magnet.

An investigation of the force of the magnetic curves was made by Professor Playfair, at the request of Professor Robison. Professor Leslie afterwards undertook the same investigation;[1] and Dr Roget[2] has more recently given a more simple demonstration of the two fundamental propositions respecting them, and has described an instrument which he has invented for the mechanical description of these curves. Mr Playfair's investigation, which is sufficiently simple, is as follows; the only change which we have made upon it being the substitution of the second power of the distance for the *m*th power as used by him.

PROP. Two magnetical poles being given in position, the force of each of which is inversely as the square of the distance from it, it is required to find a curve, in any point of which a needle (indefinitely short) being placed, its direction, when at rest, may be a tangent to the curve.

Fig. 38.



"1. Let A and B be the poles of a magnet, C any point in the curve required; then we may suppose the one of these poles to act on the needle only by repulsion, and the other only by attraction, and the direction of the needle when at rest will be the diagonal of a parallelogram, the sides of which represent these forces. Therefore, having joined AC and BC, let AD be drawn parallel to BC, and make $\frac{1}{AC^2} : \frac{1}{BC^2} = AC : AD$; join CD, then CDF will touch the curve in C.

"2. Hence an expression for AF may be obtained; for, by the construction, $AD = \frac{AC^3}{BC^2}$; and since $BC : AD = BF : FA$, and $BC - AD : AD = AB : AF$, we have $AF = \frac{AB \times AC^3}{BC^3 - AC^3}$.

"3. A fluxionary expression for AF may also be found in terms of the angles CAB, ABC. In CF take the indefinitely small part CH; draw AH, BH, and from C draw CL perpendicular to AH, and CK to BH; draw also BG and AM at right angles to FH. Let the angles $CAB = \varphi$ and $CBA = \psi$, then $CAH = \dot{\varphi}$ and $CBH = -\dot{\psi}$; also $CL = AC \times \dot{\varphi}$, and $CK = -BC \times \dot{\psi}$. Now $HC : CL = AC : AM = \frac{AC^2 \times \dot{\varphi}}{HC}$; and for the same reason $BG = -\frac{BC^2 \times \dot{\psi}}{HC}$. Therefore, since $AF : FB = AM : BG$, we have $AF : FB = \frac{AC^2 \times \dot{\varphi}}{HC} : -\frac{BC^2 \times \dot{\psi}}{HC}$, and $AF : AB = \sin.\dot{\psi}^2 \varphi : -\sin.\psi^2 \dot{\varphi} - \sin.\varphi^2 \dot{\psi}$; wherefore, if $AB = a$, $AF = \frac{-a\dot{\varphi}\sin.\dot{\psi}^2}{\dot{\psi}\sin.\varphi^2 + \dot{\varphi}\sin.\psi^2}$.

"4. If this value of AF be put equal to that already found, a fluxionary equation will be obtained, by the inte-

---

[1] *Geometrical Analysis.*

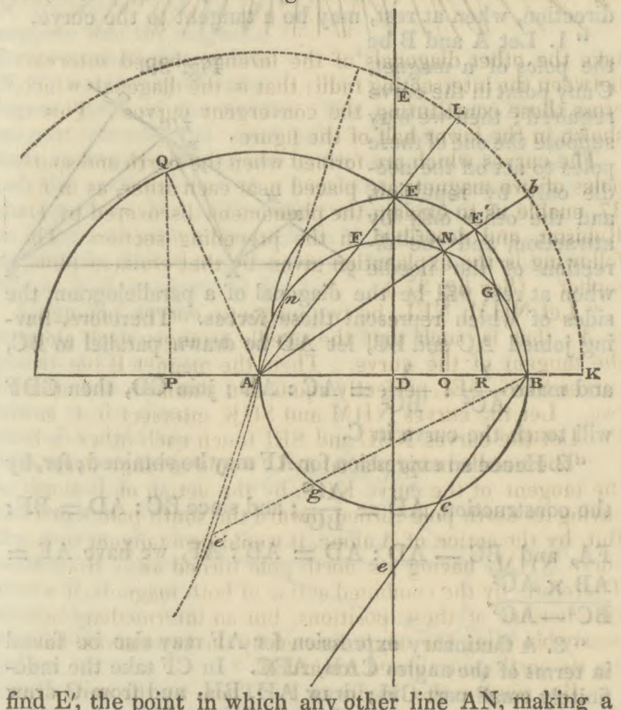
[2] *Journal of the Royal Institution of Great Britain*, vol. i. p. 311. Feb. 1831.

Laws of Magnetic Forces, &c.

gration of which the curve may be constructed. Because $AF = \frac{AB \times AC^3}{BC^3 - AC^3}$; and since $AC = \frac{a \sin. \psi}{\sin. (\varphi + \psi)}$, and $BC = \frac{a \sin. \varphi}{\sin. (\varphi + \psi)}$, we have by substitution $AF = \frac{a \sin. \psi^3}{\sin. \varphi^3 - \sin. \psi^3} = - \frac{a \dot{\varphi} \sin. \psi^2}{\dot{\psi} \sin. \dot{\varphi}^2 + \varphi \sin. \psi^2}$. Hence $\sin. \varphi^2 \times \dot{\psi} \sin. \psi^3 + \dot{\varphi} \sin. \psi^5 = - \sin. \psi^2 \times \dot{\varphi} \sin. \varphi^3 + \varphi \sin. \psi^5$, and therefore $\dot{\psi} \sin. \psi + \dot{\varphi} \sin. \varphi = 0$, and $\cos. \varphi + \cos. \psi = C$."

"5. Hence, if, beside the points A and B, any other point be given in the curve, the whole may be described. For instance, let the point E be given in the curve, and in the line DE which bisects AB at right angles. Describe from the centre A a circle through E, viz. QER, then AD being the cosine of DAE to the radius AE, the sum of the cosines of $\varphi \times \psi$ will be everywhere (to the same radius) $= 2\,AD = AB$. Therefore, to find E′, the point in which any other line AN, making a given angle with AB, meets the curve, draw from N the point in which it meets the circumference of the circle QER, NO perpendicular to AB, so that AO may be the cosine of NAO, and from O toward A take OP = AB, then AP will be the cosine of the angle ABE′; so, to find BE′, draw PQ perpendicular to AP, meeting the circle in Q; join AQ and draw BE′ parallel to AQ, meeting AE′ in E′; the point E′ is in the curve. In this way the other points of the curve may be found.

Fig. 39.

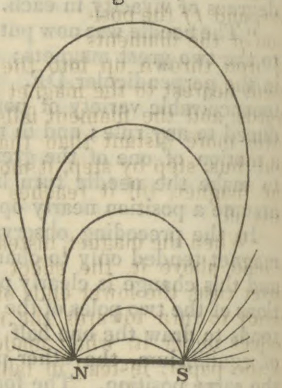


"The curve will pass through B, and will cut AB at an angle of which the cosine = RB. If then E be such, that AE = AB, the curve will cut AB at right angles. If E″ be more remote from A, the curve will make with AB an obtuse angle toward D; in other cases it will make with it an acute angle.

"A construction somewhat more expeditious may be had by describing the semicircle AFB, cutting AE in F, and AE′ in N, and describing a circle round A with the distance AL = 2AF, cutting AE′ in *b*. If BG be applied in the semicircle AFB = N*b*, BG must cut AN in a point E′ of the curve, because AN + BG = 2AF, and AN and GB are cosines of the angles at A and B.

"As the lines AN and BG may be applied either above or below AB, there is another situation of their intersection E′. Thus A*n* being applied above, and B*g* below, the intersection is in *e*′. The curve has a branch extending below A; and if D*e* be made = DE, and B*e* be drawn, it will be an asymptote to this branch. There is a similar branch below B. But these portions of the curve evidently suppose an opposite direction of one of the two magnetic forces, and therefore have no connection with the position of the needle."[1]

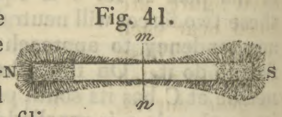
Fig. 40.



The general form of the magnetic curves is shown in fig. 40, where they are seen *converging* to the two poles N, S of the magnet NS, and changing their form with their distance from the magnet.

We have already stated that iron filings, arranged by the action of a powerful magnet, afford the finest experimental illustration of the magnetic curves. The best way to do this is to stretch a sheet of paper tightly over a wooden frame, and place it horizontally immediately above a powerful bar magnet lying on the table. Fine iron filings are now to be shaken through a gauze bag upon the surface of the paper. When the filings are thrown into a state of agitation by gently tapping upon the paper frame, they will dispose themselves into regular lines, stretching from one pole of the magnet to the other, and following the course of the magnetic curves, and exhibiting them beautifully to the eye. This effect is shown in the annexed figure, where N, S are the poles of the magnet NS, *mn* being the mean line where no filings adhere. The same arrangement is also produced when the magnet is held above the paper containing the filings.

Fig. 41.



In the case of induced magnetism, the steel filings arrange themselves in curves round the iron on which the magnetism is induced, as shown in fig. 42, where the small bar of iron is in contact with the north pole N of a magnet, *mn* being the mean line which separates the two opposite actions of the little iron bar. When the little bar of iron is placed at a distance from the magnet N, as in fig. 43, the filings arrange themselves as in that figure, *mn* being the mean line as before.

Fig. 42.

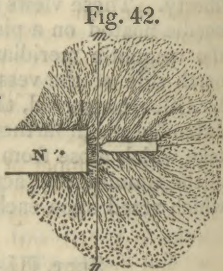


Fig. 43.

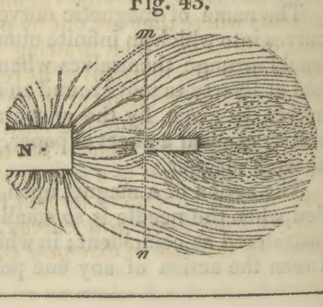


Dr Roget has given the following interesting account of the phenomena which take place by continuing to agitate the filings when they are arranged as in fig. 44.

"By continuing to tap upon the paper," says he,

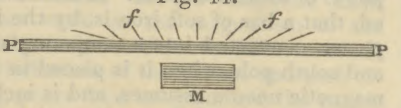
---

[1] Robison's *Mechanical Philosophy*, vol. iv. p. 350-3.

Laws of Magnetic Forces, &c.

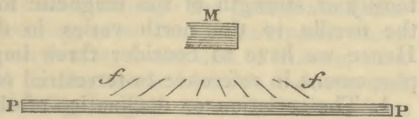
"the filings arrange themselves still more visibly into separate lines; but here a curious and perhaps unlooked-for phenomenon presents itself. The lines gradually move and recede from the magnet, appearing as if they were repelled instead of attracted, as theory would lead us to expect. This arises from the circumstance that each particle of iron, or cluster of particles, is thrown up into the air by the shaking of the paper, and, while unsupported, immediately turns on its centre, and acquires a position more or less oblique to the plane of the paper. This is shown in fig. 44, in which M represents a section of the magnet, PP a section of the paper, and *ff* the position of the filaments of iron thrown up into the air. The end of each filament nearest to the magnet is thus turned a little downwards, and the filament falls upon the paper at a point a little more distant than that which it before occupied; and thus, step by step, it moves farther and farther from the magnet, till it reaches the edge of the paper, and falls off.

Fig. 44.



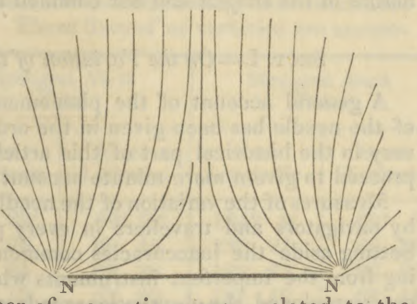
"When the magnet, instead of being beneath the paper, is held above it, the effect is just the reverse. In this latter case, the lower ends of the filaments having a tendency to turn towards the magnet, the filings gradually collect under it, when made to dance by the vibrations of the paper, instead of falling outwards as they did before. This will be seen from fig. 45, where the letters have the same indications as in the preceding figure."[1]

Fig. 45.



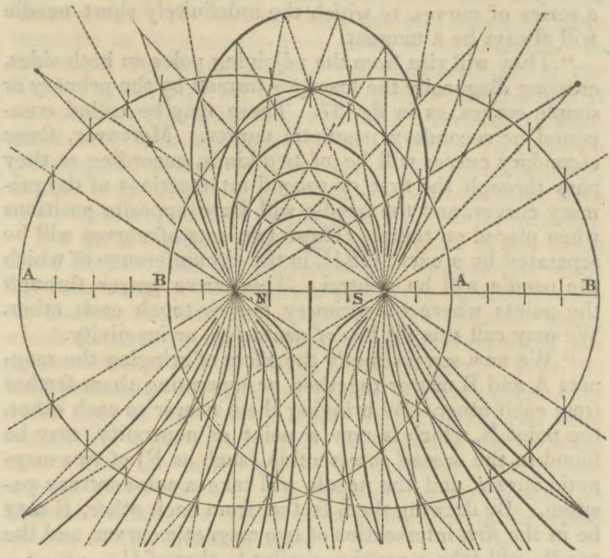
A different set of magnetic curves is produced when two similar poles, for example, two north poles, as shown in the annexed figure, are placed near each other. These curves are called *divergent* curves, and may be exhibited by iron filings like the convergent ones.

Fig. 46.



Dr Roget has given the following expeditious method of delineating a great number of magnetic curves, related to the same distance between two magnetic poles. He describes from each pole N, S, as centres, the equal of circles or semicircles AA, BB, with as large a radius as the paper will allow; and dividing the axis produced till it meets both circles, he marks off, on the circumferences of both circles, the points where they are cut by perpendiculars from these points of division; then drawing radii from the centre of each circle to the divisions of its respective circumferences, the mutual intersections of these radii will give different sets of points indicating the form of the magnetic curves which pass through them. These curves are, in the present case, composed of a succession of diagonals of the lozenge-shaped interstices formed by the intersecting radii, as shown from *convergent* curves in the upper half of the figure. In the case of *divergent* curves in fig. 46, we must take the other diagonals of the lozenge-shaped intervals between the intersecting radii; that is, the diagonals which cross those constituting the convergent curves. This is shown in the lower half of the figure.

Fig. 47.



The curves which are formed when the north and south poles of two magnets are placed near each other, as in fig. 37, enable us to explain the phenomena discovered by Dr Robison, and described in the preceding section. The following is the explanation given by that eminent philosopher. (See fig. 37.)

"Let NHM, NEL, be two magnetic curves, belonging to A; that is, such that the needle arranges itself along the tangent of the curve. Then the magnet B has two curves SGK, SEI, perfectly equal, and similar to the other two. Let the curves NHM and SGK intersect in C and F. Let the curves NEL and SEI touch each other in E.

"The needle being placed at C, would arrange itself in the tangent of the curve KGS, by the action of B alone, having its north pole turned toward the south pole S of B. But, by the action of A alone, it would be a tangent to the curve NHM, having its north pole turned away from N. Therefore, by the combined action of both magnets, it will take neither of these positions, but an intermediate one, nearly bisecting the angle formed by the two curves, having its north pole turned toward B.

"But remove the needle to F. Then, by the action of the magnet A, it would be a tangent to the curve FM, having its north pole toward M. By the action of B, it would be a tangent to the curve KFG, having its north pole in the angle MFG, or turned toward A. By their joint action, it takes a position nearly bisecting the angle GFM, with its north pole toward A. Let the needle be placed in E. Then, by the action of the magnet A, it would be a tangent to the curve NEL, with its north pole pointing to F. But, by the action of B, it will be a tangent to SEI, with its north pole pointing to D. These actions being supposed equal and opposite, it will have no verticity, or will be neutral, and retain any position that is given to it.

"The curve SEI intersects the curve NHM in P and Q. The same reasoning shows, that when the needle is placed at P, it will arrange itself with its north pole in the angle SPH; but, when taken to Q, it will stand with its north pole in the angle EQM.

"From these facts and reasonings we must infer, that, for every distance of the magnets A and B, there will be a series of curves, to which the indefinitely short needle will always be a tangent.

---

[1] *Library of Useful Knowledge*, art. *Magnetism*, p. 21.

"They will rise from the adjoining poles on both sides, crossing diagonally the lozenges formed by the primary or simple curves, as in fig. 37. These may be called compound or secondary magnetic curves. Moreover, these secondary curves will be of two kinds, according as they pass through the first or second intersections of the primary curves, and the needle will have opposite positions when placed on them. These two sets of curves will be separated by a curve GEH, in the circumference of which the needle will be neutral. This curve passes through the points where the primary curves touch each other. We may call this *the line of neutrality*, or inactivity.

"We now see distinctly the effect of bringing the magnets A and B nearer together, or separating them farther from each other. By bringing them nearer to each other, the point E, which is now a point of neutrality, may be found in the *second* intersection (such as F) of two magnetic curves, and the needle will take a sub-contrary position. By drawing them farther from each other, E may be in the *first* intersection of two magnetic curves, and the needle will take a position similar to that of C.

"If the magnets A and B are not placed so as to form a straight line with their four poles, but have their axes making an angle with each other, the contacts and intersections of their attending curves may be very different from those now represented; and the positions of the needle will differ accordingly. But it is plain from what has been said, that if we knew the law of action, and consequently the form of the primary curves, we should always be able to say what will be the position of the needle. Indeed, the consideration of the simple curves, although it was the means of suggesting to the writer of this article the explanation of those more complicated phenomena, is by no means necessary for this purpose. Having the law of magnetic action, we must know each of the eight forces by which the needle is affected, both in respect of direction and intensity; and are therefore able to ascertain the single force arising from their composition.

"When the similar poles of A and B are opposed to each other, it is easy to see that the position of the needle must be extremely different from what we have been describing. When placed anywhere in the line DF, between two magnets, whose north poles front each other in N and S, its north pole will always point away from the middle point D. There will be no neutral point E. If the needle be placed at P or Q, its north pole will be within the angle EPH, or FQI. This position of the magnets gives another set of secondary curves, which also cross the primary curves passing diagonally through the lozenges formed by their intersection. But it is the other diagonal of each lozenge which is a chord to those secondary curves. They will, therefore, have a form totally different from the former species."

CHAP. IX.—ON TERRESTRIAL MAGNETISM.

Terrestrial magnetism.

We have already seen, in preceding chapters, that a magnetic bar or needle, when either suspended by a thread, or at liberty to move freely upon a pivot, will, when all other magnetic bodies are entirely removed from it, settle in a fixed position, which, in this country, is about 25° to the west of north: this deviation of the needle from the north is called its *variation.* The very same thing will take place if a magnet or magnetised needle is placed on a piece of cork, and made to float on any fluid surface. The magnetic force by which the magnetic needle is thus made to take a fixed direction, and to return to it when it is pushed aside from that direction, has been naturally supposed to reside in the earth, and hence it has been called *terrestrial magnetism.*

But not only is a magnetised body *directed* in this manner by some unseen power; an unmagnetised body, such as a piece of iron, may be rendered permanently magnetic by the same power. This phenomenon is said to have been first observed in the vertical rod of the weather-cock of the church of the Augustines at Mantua, though others have ascribed the discovery of the fact to Gassendi. This rod had become magnetised by the continued action of the invisible power of which we speak. In later times it has been observed, that a bar of soft iron is, by the influence of the same power, converted into a temporary magnet, with a north and south pole, when it is placed in the direction which a magnetic needle assumes, and is inclined to the horizon.

If, in place of suspending the needle, or making it move horizontally on a pivot, we take an unmagnetised needle, and balance it upon a horizontal axis, then it will of course lie horizontally; but if we magnetise the needle, we shall find that it no longer remains horizontal, but takes an inclined position, or *dips*, as it is called; the *dip*, or the inclination downwards from a horizontal line, being about 70° in this country.

If we now take a magnetic needle, and suspend it by a silk fibre, we shall find, that when it is pushed out of its position of rest, it will perform a certain number of oscillations in a given time before it again takes a fixed position. When this observation is made in different latitudes, it is found that the needle is brought to rest sooner in some places than in others; which proves that the intensity or strength of the magnetic force which directs the needle to the north varies in different latitudes. Hence we have to consider three important classes of phenomena in reference to terrestrial magnetism.

1. The variation or declination of the needle, and its laws;
2. The dip or inclination of the needle;
3. The intensity of terrestrial magnetism;

of which we shall treat as perspicuously and fully as the nature of the subject and our confined limits will permit.

SECT. I.—*On the Variation of the Needle.*

Variation of the needle.

A general account of the phenomena of the variation of the needle has been given in the order of their discovery in the historical part of this article. We shall now proceed to give a more minute account of them.

Measures of the variation of the needle have been taken by navigators and travellers in every part of the globe. Setting aside the inaccuracies common to them all, arising from the imperfect instruments which were in many cases employed, the observations made on ship-board were particularly liable to error, owing to the action which the iron on board exercised upon the compass.

Halley.

The first person who attempted to collect and generalize the immense number of observations which had been made on the variation of the needle was Dr Halley, who published them in a sea-chart in 1700, in which he traced lines through all the parts of the globe where the variation was 0°, 5°, 10°, &c. These lines, which have since been called the *Halleyan lines* or *curves*, excited great interest, and had the advantage of giving, at one glance, an ocular picture of the phenomena in every part of the world. As this *Variation Chart*, however, soon became old, from the rapid changes in the variation, as well as from confused methods of observation, Messrs Mountain and Dodson collected, from the records of the admiralty, and from the papers of various naval officers, about 50,000, which they laid down in variation charts for 1745 and 1756.

The next step in the generalization of the phenomena

Churchman.

of variation was made by Mr Churchman, who published, in 1794, a programme of a *Magnetic Atlas.* He refers his variation lines to two poles, one of which he places, for the year 1800, in latitude 58° north, and longitude 134° west of Greenwich, very near Cape Fairweather; while the other pole is in latitude 58° south, and longitude 165° east of Greenwich. He supposes the northern pole to revolve in 1096 years, and the southern one in 2289 years.

Hansteen.

It is to Professor Hansteen, however, that we are indebted for the most satisfactory collection of observations on the variation of the needle, and for the most philosophical generalization of them. In the Magnetic Atlas which accompanies his work on the magnetism of the earth, he has published a variation chart for 1787, in which the irregularities and inflexions of the curves, and their total want of symmetry, prove how irregular are the causes on which terrestrial magnetism depends. In this chart, the *western line of no variation,* or that which passes through all the places on the globe where the needle points to the true north, begins in latitude 60°, to the west of Hudson's Bay, proceeds in a south-east direction through the North American lakes, passes the Antilles and Cape St Roque, till it reaches the South Atlantic Ocean, where it cuts the meridian of Greenwich in about 65° of south latitude. This line of no variation is extremely regular, being almost straight till it bends round the eastern part of South America a little south of the equator. The *eastern line of no variation* is exceedingly irregular, being full of loops and inflexions of the most extraordinary kind, indicating the action of local magnetic forces. It begins in latitude 60° south, below New Holland, crosses that island through its centre, extends through the Indian archipelago with a double sinuosity, so as to cross the equator three times, first passing north of it, to the east of Borneo, then returning to it and passing south between Sumatra and Borneo, and then crossing it again beneath Ceylon, from which it passes to the east through the Yellow Sea. It then stretches along the coast of China, making a semicircular sweep to the west till it reaches the latitude of 71°, where it descends again to the south, and returns northwards with a great semicircular bend, which terminates in the White Sea. These lines of no variation are accompanied through all their windings by other lines where the variation is 5°, 10°, 15°, &c. these last lines becoming more irregular as they recede from those of no variation. In the South Pacific Ocean, and the equatorial part of the North Pacific, they are so little dependent on the lines of no variation, that they form returning curves of an elongated oval form, the curves of 2°, 3°, 4°, 5°, 6°, and 7°, crossing the equator and the tropic of Capricorn twice, so that, in the centre or axis of the ovals which these lines form, there should be a fragment of a line of no variation.

Barlow.

The great changes which had taken place in the variation since 1787, and the number of new observations which had been made in every part of the world, induced Professor Barlow, in 1833, to construct a new variation chart, which forms a very interesting and valuable record of the present state of our knowledge on this subject.[1] With the kind permission of Professor Barlow, we have given a reduced copy of this chart in Plate CCCXXVII., and have included in it his separate polar projection of the variation lines within the arctic zone. When compared with the account given above of the two lines of no variation in Hansteen's chart, the motion of these lines, and of the whole system, will be distinctly seen.

In the charts both of Hansteen and Barlow the variation lines exhibit a convergency at their extremities;[2] and Hansteen considers it proved that there are *four points of convergency,* two in each hemisphere, a weaker and a stronger, on opposite sides of the poles of revolution. These four points he considers as the *four magnetic poles* of the globe; and, by comparing observations which have been made at different times, he concludes that they have a regular motion round the globe, the two northern ones from west to east, in an oblique direction, and the two southern ones from east to west, also obliquely. The following are the periods of their revolution, as calculated from the best observations previous to 1817, when his work was published:

The *strongest* NORTH pole in 1740 years.
The *strongest* SOUTH pole in 4609 years.
The *weakest* NORTH pole in 860 years.
The *weakest* SOUTH pole in 1304 years.

Upon these data he computed the following table, showing the position of these poles from 1800 to 1850:

Years.	Strongest *North* Pole.		Strongest *South* Pole.		Weakest *North* Pole.		Weakest *South* Pole.	
	West Longitude.	North Latitude.	East Longitude.	South Latitude.	East Longitude.	North Latitude.	West Longitude.	South Latitude.
1800	93° 33′	69° 53′	134° 8′	69° 7′	131° 43′	85° 25′	130° 28′	77° 50′
1810	91 28	69 45	133 21	68 59	135 54	85 18	133 14	78 3
1820	89 24	69 38	132 35	68 52	140 6	85 12	135 59	78 16
1830	87 19	69 30	131 47	68 44	144 17	85 6	137 45	78 29
1840	85 15	69 22	131 1	68 37	148 28	85 0	140 31	78 41
1850	83 10	69 14	130 14	68 29	152 40	85 0	143 16	78 54

Hansteen remarks, that the four periods above mentioned, viz. 860, 1304, 1740, and 4609, become, by a slight alteration, 864, 1246, 1728, and 4820; and he adds, rather fancifully for a matter of science, that these numbers are equal to 2 × 432, 3 × 432, 4 × 432, and 10 × 432, and that the number 432 is one of the most important among the sacred numbers of the Indians, Babylonians, Greeks, and Egyptians, which are said to depend on certain combinations of natural events. According to the mythology of the Brahmins, the duration of the world is divided into four periods; the first of which is 432,000 years; the second, 2 × 432,000; the third, and so in all $(1 + 2 + 3 + 4) = 10 \times 432{,}000$. Hansteen also considers it worthy of remark, that the sun's mean distance from the earth is 216 (the half of 432) radii of the sun, the moon's mean distance 216 radii of the moon, and, what he says is still more striking, $60 \times 432 = 25920$, the smallest number divisible at once by all the four periods; and hence, he adds, the shortest line in which all the four poles can accomplish a cycle, and return to the same state as at present, *coincides exactly with the period in which the precession of the equinoxes will amount to a complete circle*, reckoning the precession at a degree in seventy-two years.

---

[1] See *Philosophical Transactions,* 1833, p. 667–675, and plates xvii. and xviii.

[2] Professor Barlow has inserted the magnetic observations of Commander Ross; and he remarks, that the very spot where this officer found the needle perpendicular, "that is, the pole itself, is precisely that point in my globe and chart in which, by supposing all the lines to meet, the several curves would best preserve their unity of character, both separately and conjointly, as a system." The exact place of the pole is laid down in the accompanying chart, Plate CCCXXVII.

Hansteen considers the four poles as originating in *two* magnetic axes, the two strongest being the termination of one axis, and the two weakest, of the other; and he conceives that they may have been produced either along with the earth itself, or at a later epoch. According to the first supposition, it is not easy to account for their change of position; but according to the last, they must have originated either from the earth alone, or from some external cause. If they originated in the earth, their change of position is still unsusceptible of explanation; and hence Hansteen conceives that they have their origin from the action of the sun heating and illuminating the earth, and producing a magnetic tension, as it produces electrical phenomena.

Since the publication of Professor Hansteen's work, the valuable observations made during the British voyages of discovery in the arctic regions have been given to the world; and, by availing himself of these, and obtaining access to others unpublished in the marine chart office at the Admiralty, the Norwegian philosopher has obtained more accurate determinations both of the positions and periods of revolution of the magnetic pole. The following is a brief abstract of his calculations.

1. *Strongest north pole.* In 1813 the observations made on board his majesty's ship Brazen, in Hudson's Bay, give 67° 10′ for the latitude of the strongest north magnetic pole, and 92° 24′ for its west longitude. Hence, by comparing this with previous determinations, we have

	Latitude of Pole.	West Longitude of Pole.
1730	70° 45′	108° 6′
1769	70 17	100 2
1813	67 10	92 24

From these data we obtain the motion of the pole to the east.

Epochs.	Years.	Change of Place in Longitude.	Annual Motion.
From 1730 to 1769	39	8° 4′	12′ 44″
1769 to 1813	44	7 38	10 41

From which we obtain

Mean annual motion of the pole .... 11′ 4″·25

Period of complete revolution .... 1890 years.

In August 1819, Captain Parry was to the north of this pole, and found the dip to be 88° 37′, and on the 11th September he was three degrees west of the pole. Hence, as his latitude was then 74° 27′, the latitude of the pole must have been about 71° 27′.

According to the more recent observations of Commander Ross, this pole, upon which he erected a flag, is situated in north latitude 70° 5′ 17″, and west longitude 96° 45′ 48″, which coincides strikingly with Hansteen's result.

2. *Strongest south pole.* By combining the observations of Cook in 1773 and 1777, with those of Furneaux in 1773, and comparing these with Tasman's observations in 1642, Hansteen has found the following position of it.

	Motion in 131 Years.
1642, north lat. 71° 5′; east long. 146° 57′	10° 14′
1773, north lat. 69° 26′ 5′; east long. 136° 15′ 4″	

Hence the real motion of this pole in 131 years is 10° 14′, or 4′·67 annually, and its period of complete revolution will be 4605 years.

3. *Weakest north pole.* By comparing observations made in 1770 and 1805, at Tobolsk, Tara, and Udinsk, in Siberia, Professor Hansteen found—

	North Latitude.	East Longitude.	Motion in 35 Years.	Annual Motion.
1770,	85° 46′	91° 29′ 30″	14° 35′	35′·128
1805,	85 21½	116 19		

Hence this pole completes its revolution from east to west in 860 years.

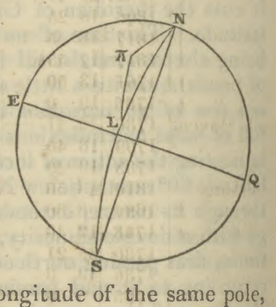
4. *Weakest south pole.* By comparing observations made by Cook and Furneaux in 1774, with those recorded by Halley as made in 1670, Hansteen obtained the following results:

	South Latitude.	West Longitude.	Motion in 104 Years.	Annual Motion.
1670,	64° 7′	94° 33½′	28° 43½′	16′·57
1774,	77 17	123 17		

Hence this pole completes its revolution from east to west in 1303 years.

Professor Barlow has endeavoured to deduce the position of the magnetic pole, upon the supposition that the magnetic phenomena of the earth are analogous to those exhibited by a simple iron ball. The tangent of the dip being equal to double the tangent of the magnetic latitude, Mr Barlow supposes π to be the magnetic pole, N, S the terrestrial poles, and L a known place where the dip and variation have been well ascertained. Then by the dip we obtain the magnetic latitude πL; NL being the terrestrial latitude, and NLπ the variation. Hence, in the spherical triangle NLπ, we have two sides and the contained angle to find the side Nπ the terrestrial latitude of the magnetic poles, and πNL the longitude of the same pole, in reference to the meridian NL.

Fig. 48.



In making this computation, Mr Barlow selected a certain number of the best observations on the dip and variation of the needle, made in different parts of the world, and he obtained the following results:

Place of Observation.	Date.	Dip.	Variation.	Computed Place of Magnetic Pole. North Lat.	Computed Place of Magnetic Pole. West Long.
Tristan d'Acunha	1821	37° 53′ S.	12° 0′ W.	70° 56′	49° 33′
Trinidad	1821	10 27 N.	5 0 W.	73 59	47 20
St Jago	1820	48 0 N.	15 55 W.	69 37	67 4
Teneriffe	1820	58 22 N.	20 47 W.	69 49	69 14
Madeira	1820	63 47 N.	23 7 W.	68 4	65 26
Madrid	1799	67 41 N.	19 59 W.	72 47	50 33
Paris	1814	68 36 N.	22 34 W.	75 31	67 4
London	1818	70 34 N.	24 30 W.	75 2	67 41
Berlin	1805	69 53 N.	18 2 W.	79 2	70 44
Copenhagen	1813	71 26 N.	18 22 W.	79 43	67 38
Davis' Straits	1820	83 43 N.	60 20 W.	67 37	94 26
Regent's Inlet	1820	88 26 N.	118 16 W.	71 10	98 16
Baffin's Bay	1820	84 30 N.	82 2 W.	71 13	97 3
Possession Bay	1820	86 4 N.	108 46 W.	69 40	99 10
Melville Island	1820	88 43 N.	127 46 E.	73 12	102 46

Among these results there is a discrepancy of no less than 55° in longitude, and 10° in latitude; and hence Mr Barlow concludes that every place has its particular polarising axis, which probably in all cases falls within the frigid zones, varying within these limits through all possible degrees of latitude and longitude.

These aberrations Mr Barlow ascribes to local inequalities in the distribution of the ferruginous parts of the terrestrial sphere.

The following tables contain the best measures of the variation of the needle. Table XI., containing the observations collected by Hansteen since the publication of his work, was communicated to the writer of this article by that eminent philosopher.

On the progressive Changes in the Variation of the Needle.

Change in the variation.

We have already seen that the variation of the needle experiences a progressive change in every part of the globe. The following table shows very satisfactorily the change which has taken place in London.

Table of the Variation at London from 1576 *to* 1831.

Years.	Observers.	Variations.	
1576	Norman	11° 15′	easterly.
1580	Burroughs	11 17	maximum.
1622	Gunter	6 12	
1634	Gellibrand	4 5	
1657 1662		0 0	No variation.
1666		0 34	westerly.
1670		2 6	
1672		2° 30′	westerly.
1700		9 40	
1720		13 0	
1740		16 10	
1760		19 30	
1774		22 20	
1778	*Phil. Trans.*	22 11	
1790		23 39	
1800		24 36	
1806	*Phil. Trans.*	24 8	
1813	Col. Beaufoy	24 20 17″	
1815	Ditto	14 27 18	maximum.
1816		24 17 9	
1820		24 11 7	
1823		24 9 40	
1831		24 0 0	

The following table shows the progressive change in the variation of the needle at Paris.

Table of the Variation at Paris from 1541 to 1829.

Years.	Variations.	Years.	Variations.
1541	7° 0′ easterly.	1683	3° 50′ westerly.
1550	8 0	1700	7 40
1580	11 30 maximum.	1750	17 15
1603	8 45	1767	19 16
1618	8 0	1780	20 35
1630	4 30	1785	22 0
1640	3 0	1800	22 12
1659	2 0	1807	22 34
1664	0 40	1814	22 54
1669	0 0 No variation.	1819	22 29
1667	0 15 westerly.	1824	22 23
1670	1 30	1829	22 12·5 Arago.
1680	2 40		

The following table shows the progressive change in the variation in the southern hemisphere since the time of Vasco de Gama.

Table of the Variation at the Cape of Good Hope.

Years.	Variations.	Years.	Variations.
1605	0° 30′ easterly.	1724	16° 27′ westerly.
1609	0 12 westerly.	1752	19 0
1614	1 30	1768	19 30
1667	7 15	1775	21 14
1675	8 30	1791	25 40 maximum.
1702	12 50	1804	25 4

Professor Hansteen has explained these progressive changes in the variation of the needle by the motion of the four magnetic poles. Taking the variations at Paris for the northern hemisphere, he remarks that in 1580 the weak north pole in Siberia was about 40° east of Greenwich, or to the north of the White Sea, while the strong American pole was about 136° west of Greenwich, or 36° east of Behring's Straits. The west pole, therefore, lay *nearer* Europe than now, and the strong one *more remote.* Hence the action of the former predominated, and drew the needle eastward. But the *weak* pole now withdrew itself towards the Siberian Ocean, from Europe, and the *strong one* approached it. The action of the latter therefore predominated, and the needle turned westward till 1814, when it reached its greatest declination, and commenced its easterly course.

The explanation is equally satisfactory in reference to the southern hemisphere, and the variation at the Cape. In 1605 the *weak* south pole was 76½° west of Greenwich, and the *strong* south pole about 150° east of that meridian. The weak pole was, therefore, much *nearer* the Cape than now, while the stronger pole was *more remote* from it. The influence of the *weak* pole was therefore most powerful, so that the south pole of the needle moved towards the west, and its north pole more towards the east. But when the *weak* south pole receded from the Cape, and the *strong* one approached it, the south pole of the needle turned more and more towards the strong pole, and its declination became consequently more westerly.

Mr Barlow has therefore given the following rule for calculating the variation of the needle, on the supposition that the magnetic pole which governs the needle in London was in 1818 in north latitude 75° 2′, and west longitude 67° 41′, and that its motion was uniform at the rate of 4° 14′ in *ten* years, the variation being 0°, or the pole being in the meridian of London, in 1660.

Rule. To the co-tangent of half the angle πNL (see the last figure), add the constant log. 1·65642; find the angle of which the sum is the tangent, and call it arc (A). To the same co-tangent add the log. 0·03987, and find the arc of which the sum is the tangent, and call it arc (B). Then B — A will be the variation, or the angle πLN. The following comparison of the variations thus computed with actual observation is very interesting.

Years.	Variations.		Differences.	Observers.
	Observed.	Computed.		
1660	0° 0′	0° 0′	0° 0′	Bond.
1670	2 30	2 44	0 14 +	Halley.

1828		24 29		
1833		24 26		

The numbers in the column of differences are very small, and may arise as much from errors of observation as from a defect in the theory. The average difference is only about 45′.

Mr Barlow has computed the variation also for Paris and Copenhagen, and compared it with the best observations made at these places. The average difference for Paris is less than 30′. At Copenhagen it is 37′, or only 20′ if we throw aside the observed variation for 1731, which seems to err greatly in defect.

On the Annual Variation of the Needle.

Annual variation. Cassini.

Besides the progressive changes in the declination of the needle, M. Cassini observed an *annual* change, depending on the position of the sun in reference to the equinoctial and solstitial points.

Between the months of *January* and *April* the magnetic needle recedes from the north pole of the globe, so that its western declination increases.

From *April* to the beginning of *July*, that is, from the vernal equinox to the summer solstice, the declination diminishes, or the needle approaches the north pole of the globe.

From the summer solstice to the vernal equinox, the needle, receding from the north pole, returns to the west, so that in October it has nearly the same position as in May, and between October and March the western motion is smaller than in the three preceding months.

Hence it follows, that during the *three* months between the vernal equinox and the summer solstice, the needle retrogrades towards the east; and during the following *nine* months its general motion is towards the west.

Arago.

This important subject has particularly occupied the attention of M. Arago. Taking the mean declination of each day, or that of the maximum and minimum, and the mean declination of each month, he has arranged in tables the mean monthly declinations at Paris from 1784 to 1788, and also those at London, near the equinoxes and solstices, from 1793 to 1805, as calculated from the observations of Mr Gilpin, and, by a comparison of the results, he finds a maximum of declination towards the vernal equinox, and a minimum towards the summer solstice; but this difference was less at London than at Paris.

In comparing the observations of Cassini in 1786 with those of 1800, corresponding to the measures of Gilpin, M. Arago has found that they do not differ from one another in their magnetical relations, but in one point. In 1786 the annual change of declination was nine minutes, whereas in 1800 it was scarcely a minute. Hence, says he, it is worthy of remark, that the retrograde motion which the needle experiences between the vernal equinox and the summer solstice decreases at the same time with the general and annual motion towards the west.

At Salem in Massachusetts, where observations were made in 1810 by M. Bowditch, the declination is west, and has diminished for a great number of years about two minutes annually. In examining these observations, M. Arago does not find any trace of the period of Cassini. The declination has never diminished between the vernal equinox and the summer solstice, but it gradually increases from April to August. This increase is compensated by a decrease of the declination between September and December, so that the period seems to be transferred from spring to autumn. If this idea shall be found correct, M. Arago conceives that the annual changes will be regulated by the following principles.

1. When the needle, having a westerly declination, recedes from the meridian, it experiences a retrograde motion, which brings it back to this place. This is the discovery of Cassini.

2. This retrograde oscillation is greater in proportion as the annual change of declination is greater; a result deducible from a comparison of Cassini and Gilpin's observations.

3. The oscillation disappears, and every month gives nearly the same mean declination, when, the needle having arrived at the limit of its western digression, the annual change of declination becomes nothing. This result is deducible from Colonel Beaufoy's observations.

4. When the westerly declination diminishes from year to year, no remarkable oscillations are observed in the needle towards the east, excepting between the months of September and December. This is the observation of Mr Bowditch. According to Colonel Beaufoy's observations, the daily variation is greatest in *June* and *August*, and less in July, so that the annual curve has two *maxima* and two *minima* in the course of the year, the two maxima being in June and August, and the two minima in December and July.

On the Diurnal Variations of the Needle.

Diurnal variation.

That there is a daily change in the variation of the needle, as originally discovered by Mr Graham in 1724, has been placed beyond a doubt by observations made with the most accurate instruments in almost every part of the world. The following table contains the mean diurnal changes in the variation, according to the observations of Canton in 1759, of Gilpin in 1787 and 1793, and of Colonel Beaufoy in 1817–19.

Table of the Mean Daily Changes in Variation.

Months.	Observations of Canton. 1759.	Observations of Gilpin.		Colonel Beaufoy. 1817–18–19.
		1787.	1793.	
January	7′ 8″	10′ 2″	4′ 3″	5′ 3″
February	8 58	10 4	4 6	6 3
March	11 17	15 0	8 5	8 22
April	12 26	17 4	11 7	11 48
May	13 0	18 9	10 4	9 53
June	13 21	19 6	12 6	11 15
July	13 14	19 6	12 5	10 43
August	12 19	19 4	12 1	11 26
September	11 43	15 5	9 8	9 44
October	10 36	14 3	7 0	8 46
November	8 9	11 1	3 8	7 10
December	6 58	8 3	3 8	4 7
Mean daily change	10 43	14 39	8 0	9 32

The following Table shows the Amount of the Daily Variation at other Places compared with that at London.

London, general mean	60′	44″	
Geneva	15	42	Saussure.
Chamouni	17	6	
Col du Geant	15	43	
Freiberg	12	11·9	
Petersburg	12	10·1	
Nicolajef	10	53·4	
Kasan	70	36·5	

When the diurnal variation of the needle was first discovered, it was supposed to have only two changes in its movements during the day. About seven A. M. its north end began to deviate to the west, and about two P. M. it reached its maximum westerly deviation. It then returned to the eastward to its first position, and remained stationary till it again resumed its westerly course in the following morning. When magnetic observations became more accurate it was found that the diurnal movement commences much earlier than seven A. M. but its motion is to the east. At half past seven A. M. it reaches its greatest easterly deviation, and then begins its movement to the west till two P. M. It then returns to the eastward till the evening, when it has again a slight westerly motion; and in the course of the night, or early in the morning, it reaches the point from which it set out twenty-four hours before. The most accurate observations made in England were those of Colonel Beaufoy, when the variation was about 24½ west. In these the absolute maxima were earlier than in Canton's observations, and the second maxima west about eleven P. M.

The following were the diurnal changes observed at Paris. During the night it is nearly stationary. At sunrise its north extremity moves to the westward, as if it were avoiding the solar influence. Towards noon, or more generally from noon to three o'clock, it attains its maximum westerly deviation, and then it returns eastward till nine, ten, or eleven o'clock in the evening; and then, having reached its original position, it remains stationary during the night. The amount of this daily variation is, for April, May, June, July, August, and September, from 13′ to 15′, and for the other six months of the year from 8′ to 10′. On some days it rises to 25′, and on others it does not exceed 5′ or 6′.

According to M. Dove, the maximum easterly deviation of the needle takes place at eight A. M. at Freiberg, Nicolajef, and St Petersburg, and at nine A. M. at Kasan; and the maximum of westerly deviation at two P. M. at Kasan, Nicolajef, and St Petersburg, and at one P. M. at Freiberg.

In the northern regions, such as Denmark, Iceland, and Greenland, the diurnal variations are greater, and less regular. The needle is not stationary during the night, and it does not reach its maximum westerly deviation till between eight and ten P. M., and its most easterly about nine or ten A. M.

In advancing from the north to the magnetic equator, the diurnal variation diminishes in amplitude, and it ceases to be perceptible in the magnetic equator. Captain Duperrey, however, has found, that when the place is either under the magnetic equator, or at a little distance from it, the north point of the needle advances every morning to the *west* or to the *east*, according as the sun passes to the *north* or to the *south* of the place of observation.

In the southern magnetic hemisphere the daily variation takes place in an opposite manner, the *north* end of the needle moving to the east at the same hours that it did to the west in the northern hemisphere; a result which has been established by the observations of Mr J. Macdonald at St Helena, and at Fort Marlborough in Sumatra.[1] M. Mr Macdonald observes, that the diurnal variations are sensibly less between the tropics than in Europe.

---

[1] Made in 1794, 1795, and 1796; see *Philosophical Transactions.*

Freycinet was led to the same result by observations made in the Isle of France, Timor, Rawak, Guham, Mowi, Port Jackson, and other places. At the Marianne and Sandwich Isles, in the northern hemisphere. the *north* point of the needle moves to the west, as in Europe, from eight A. M. till one P. M. though the variation there is easterly. At Timor, Rawak, and Port Jackson, to the south of the equator, the north point of the needle moves during the morning in an opposite direction; hence the observations made to the north of the line agree with those in Europe, while those in the southern hemisphere, like those of Macdonald, exhibit an opposite motion. M. Freycinet found that the diurnal oscillations have a small amplitude between the tropics. At Rawak, only the fortieth of a degree south of the equinoctial line, M. Freycinet found that the needle oscillated every day with an amplitude of 3′; so that it is the magnetic, and not the terrestrial, equator, as Duperrey afterwards found, which separates the zone of westerly from the zone of easterly diurnal variations.

Observations are still wanting to show whether or not the daily variations have the same direction in places where the variation is westerly and in those where it is easterly.

The dipping needle also undergoes, as will be afterwards seen, daily variations, but their amplitude is of less amount. There can be no doubt, as M. Pouillet observes, that a needle capable of moving in any given azimuth will experience daily changes; and that a needle moveable in every direction round its centre of gravity would describe every day a cone whose base would be an ellipse, or some other curve more or less elongated, in different parts of the earth.

Cause of the diurnal variation.

The sun is now universally allowed to be the cause of the diurnal variations of the needle. Canton ascribed them to the action of solar heat, having ascertained that heat tends to diminish the attractive powers of a magnet, and assuming that the direction of the needle was due to the resultant of all the magnetic forces of the terrestrial sphere. When the sun was to the eastward of the needle, the forces lying to the eastward suffered a diminution of power, in consequence of which the westerly force prevailed, and the north end deviated to the west. When the sun, on the other hand, was to the westward of the needle, the power on that side diminished, and the needle returned again to the eastward. Canton, however, did not give any explanation of the morning easterly variation of the needle.

On the Irregular Motions of the Magnetic Needle as produced chiefly by the Aurora Borealis.

Irregular motions of the needle produced by the aurora borealis.

Besides the regular changes of an annual and diurnal nature to which the needle is subject, it is sometimes affected with sudden and extraordinary movements, to which Baron Humboldt has given the name of *magnetic hurricanes*, during which the needle traverses with a shivering motion, and often oscillates several degrees on each side of its mean position.

These sudden and capricious motions have been most frequently observed during the existence of the *auroræ boreales*, and have therefore been ascribed to that cause. The influence of this meteor on the magnetic needle was first noticed by Wargentin in 1750. It was observed by Bergman and others; and Van Swinden remarks, that he seldom failed to observe auroræ boreales after any anomalous motion of the needle; and he always concluded that there must have been one at the time, though he did not see it. As needles made of other substances, such as copper or wood, have not been found to be affected, the action of the aurora cannot be considered as an electrical one.

Dr Dalton's observations.

The influence of the aurora on the needle has been particularly studied by Dr Dalton, who has stated his views in his *Meteorological Observations and Essays*, published in 1793, in a dissertation of great ability, which has never received the notice which it merits. He has shown that the luminous beams of the aurora are parallel to the dipping needle; that the rainbow-like arches cross the magnetic meridian at right angles; that the broad arch of the horizontal light is bisected by the magnetic meridian; that the boundary of a limited aurora is half the circumference of a great circle crossing the magnetic meridian at right angles, the beams perpendicular to the horizon being only those on the magnetic meridian.

Dr Dalton has shown, from numerous observations, that the aurora exercises an irregular action on the magnetic needle; and he has deduced from these observations the following results:

1. When the aurora appears to rise only about 5°, 10°, or 15° above the horizon, the disturbance of the needle is very little, and often insensible.

2. When it rises up to the zenith, and passes it, there never fails to be a considerable disturbance.

3. This disturbance consists in an irregular oscillation of the horizontal needle, sometimes to the eastward and then to the westward of the mean daily position, in such sort that the greatest excursions on each side are nearly equal, and amount to about half a degree each at Kendal.

4. When the aurora ceases, or soon after, the needle returns to its former station.

Professor Hansteen's observations on the magnetical influence of the aurora are peculiarly interesting. He states, that the extraordinary shivering movements of the needle are perhaps never exhibited except when the aurora is visible; and that this disturbance seems to operate at the same time in places the most widely separated. The extent of these movements may in less than twenty-four hours amount to five or five and a half degrees. In such cases, he adds, the disturbance is also communicated to the dipping needle; *and as soon as the crown of the aurora quits the usual place (the points where the dipping needle produced would meet the sky), that instrument moves several degrees forward*, and seems to follow it. After such disorders, he continues, the mean variation of the needle is wont to change, and not to recover its previous magnitude till after a new and similar disturbance. During the continuance of the aurora borealis, the intensity of the earth's magnetic force seems to grow weaker; for which reason the needle recedes from that magnetic pole where the ray of the aurora is displayed.

The influence of the aurora borealis on the needle has been studied with particular care by M. Arago, whose accurate and regularly continued series of observations on the daily changes of the magnetic needle at Paris has enabled him to compare these changes with the occurrence of the northern light. The following is an abstract of his views on the subject: The appearance of an aurora causes the magnetic needle to vary several degrees to the east and west of its mean position. In the region were it appears, luminous beams, differently coloured, shoot up from all points of the horizon; *and the part of the heavens where all these beams or radiations unite is precisely that to which a magnetic needle directs itself when suspended by its centre of gravity.* M. Arago has also shown that the concentric circles, which show themselves almost always before the luminous beams, rest each upon the two points of the horizon equally distant from the magnetic meridian, *and that the most elevated points of each arch are exactly in this meridian.* From these two facts he concludes that there is a relation between the causes of the aurora borealis and the motions of the magnetic needle; and, from observations made in places remote from each other, he infers that the aurora acts even before it shows itself in the horizon, and that its influence is exerted at very considerable distances. In a subsequent paper on the subject, M. Arago shows that the auroras

Terrestrial Magnetism.

which are visible only in America, at St Petersburg, and in Siberia, in spite of the immense distance which separates us from these regions, produces a perceptible derangement of the magnetic needle at Paris. M. Arago at first believed that even the auroras of the southern hemisphere extended their influence to Paris; but he has since found, that on the days when these southern auroræ took place, the phenomenon was observed also in the north, so that no conclusion can be properly deduced from this coincidence with the observed derangements of the needle.

M. Kupffer has confirmed by his own observations the first results obtained by M. Arago, and is of opinion that the aurora extends its influence to a great distance. When the needle was driven from its mean position by the influence of this meteor, M. Kupffer could not perceive any sensible difference between the duration of an oscillation at this time and at any other. He has, however, excepted some cases where the deviation was very considerable; but what was very remarkable was, that when the needle deviated to the east, the duration of an oscillation was greater than usual, whilst on the 24th November 1825, when the needle deviated to the west, the duration of an oscillation was smaller. On the other hand, the dip being in the ratio of the duration of the oscillation, the preceding observations seem to prove that the dip diminishes when the needle deviates to the west, and increases with an easterly deviation.

Notwithstanding the body of evidence which proves the connection between the aurora and the derangement of the needle, it is a very remarkable fact, that during the frequent occurrence of that meteor at Port Bowen, Captain Foster did not observe any peculiar changes in the deviation of the needle, although, from his vicinity to the magnetic pole, the diurnal variation sometimes amounted to 4° or 5°, and it was to be presumed that the slightest action of the aurora would, under such circumstances, have been visible. From these observations of Captain Foster and others, the natural conclusion is, that there are some auroræ which do not disturb, while there are others which do disturb, the magnetic needle.

During Captain Back's residence at Fort Reliance (north latitude 62° 46′ 29″, and west longitude 109° 0′ 39″) for *six* months in 1833–4, and *four* months in 1834–5, the aurora occurred almost every night. The magnetic needle seems to have been constantly affected by it, and on one occasion the effect exceeded *eight degrees.* "Brilliant and active coruscations of the aurora borealis," says Captain Back, "when seen through a hazy atmosphere, and exhibiting the prismatic colours, almost invariably affected the needle. On the contrary, a very bright aurora, though attended by motion, and even tinged with a dullish red and a yellow, in a clear blue sky, seldom produced any sensible change, beyond, at the most, a tremulous motion.

"A dense haze or fog, in conjunction with an active aurora, seemed uniformly favourable to the disturbance of the needle; and a low temperature was favourable to brilliant and active coruscations. On no occasion, during two winters, was any sound heard to accompany the motions. The aurora was frequently seen at twilight, and as often to the eastward as to the westward. Clouds, also, were often perceived in the day time, in form and disposition very much resembling the aurora."

Mr Christie has explained the absence of any apparent action of the aurora, by the supposition that the apparatus employed was not fitted to exhibit that action; and he entertains therefore the opinion, "that changes in the deviation and intensity of the terrestrial forces are simultaneous with the aurora borealis." The following is the method recommended by Mr Christie for observing the effects of the aurora to the greatest advantage:

"If the magnetic forces brought into action during an aurora are in the direction of the magnetic meridian, they will affect a dipping needle adjusted to the plane of that meridian; but the direction of an horizontal needle will remain unchanged. On the other hand, if the resultant of these forces makes an angle with the meridian, the direction of the horizontal needle will be changed, but the dipping needle may not be affected. In order to determine correctly the negative influence of the aurora, by means of an horizontal needle, it is therefore necessary not only to have regard to those forces which influence its direction, but likewise to those which affect the horizontal intensity. The effects of the former are the objects of direct observation, but those of the latter are not so immediately observable. As, during an aurora, the intensity may vary at every instant, and it is these changes which are to be detected, the method of determining the intensity by the time of vibration of the needle cannot here be applied, and other means must be adopted. The best method appears to me to be that which I employed for determining the diurnal variation of the horizontal intensity, the needle being retained nearly at right angles to the meridian by the repulsive force of a magnet, or by the torsion of a fine wire or thread of glass. For the purpose, then, *of detecting, in all cases, the magnetic influence of the aurora*, I consider that two horizontal needles should be employed; one adjusted in the meridian, for determining the changes which may take place in the direction of the horizontal force, and the other at right angles to the meridian, to determine the changes in the intensity of that force, arising principally from new forces in the plane of the meridian, and which would affect the direction of the dipping needle alone. Both these needles should be delicately suspended, either by very fine wire, or by untwisted fibres of silk. In order to render the changes in the direction of the needle in the meridian more sensible, its directive force should be diminished by means of two magnets north and south of it, and having their axes in the meridian. These magnets should be made to approach the needle until it points about 30° on either side of the meridian, and they should be so adjusted that the forces acting upon the needle will retain it *in equilibrio*, with its marked end at about 30° to the east and 30° to the west of north, and also at south. The needle is to be left with its marked end pointing south, for the purpose of observing the changes occurring in its direction. If magnets are employed to retain the second needle nearly at right angles to the meridian, they should be made to approach its centre until the points of equilibrium are at about 80° east, 80° west and south, the observations being made with the needle at 80° east and 80° west. An objection to this method of adjusting this needle by means of magnets is, that any change in their temperature will have a very sensible effect on the direction of the needle in this position; and should such change take place during the observations, corrections must be applied to the results before any accurate conclusions can be drawn from them. I have before remarked, that this inconvenience will be in a great measure obviated by employing the torsion of a fine wire, or a very fine plummet of glass, to retain the needle at about 80° from the meridian. In this case, the ratio of the force of torsion to the terrestrial force acting upon the needle having been determined, a measure will be obtained of the changes which take place in the intensity of the terrestrial force during the occurrence of an aurora. It is very desirable that it should be ascertained whether the effects on the needle are simultaneous with any particular class of phenomena connected with the aurora; whether these effects are dependent on the production of beams or coruscations, or on the formation of luminous arches; or whether any difference exists in the effects produced by them. In order to determine this, it is necessary that the times of the occurrence of the different phenomena, and also of the changes in the directions of the needles, should be accurately noted; and for such observations three observers appear to be indispensable."

It has become a question of some importance, whether the electric state of the clouds produces any effects upon the needle: and this question has increased in interest since the discovery of the magnetical effects of galvanic and common electricity. Mr Christie has made some valuable observations on this subject. Adjusting in a particular manner a needle between two magnets, so that its directive force was considerably diminished, he found that changes in the position of electric clouds were accompanied by changes in the position of the needle. Captain Sir Everard Home also observed, that, in two instances, a vibrating needle came sooner to rest during a thunder storm than it did either before or after it. The number of vibrations was reduced in one case from 100 to 40, and in another from 200 to 120.

An analogous fact was observed by Captain Back, in 1833, at Fort Alexander, at the southern extremity of Lake Winnipeg, where a "considerable alteration appeared, both in the number of vibrations, and the point at which the needle finally rested. A second time showed a similar discrepancy. The reason of this peculiarity I could not divine, until about an hour afterwards, when some gentlemen arrived from the westward, and acquainted us that they had just encountered a severe thunder shower, though the sky over the fort underwent no visible change, and wore the same sultry aspect as it had done most of the forenoon."[1]

The view which we have given, in a subsequent section, of the magnetic condition of our atmosphere, arising from the uniform dissemination of ferruginous and other metallic matter, enables us to give a satisfactory explanation of the general phenomena of the aurora, of its action on the needle, and of the circumstances under which it will affect or not affect its stability. That there is magnetic matter in the atmosphere is indubitable, and that this matter may be heated by the electricity of the atmosphere, so as to give out light of different colours, and may have its magnetic influence increased or diminished by this electrical action, as well as by ordinary changes of temperature, cannot be doubted. When the magnetic forces are in a state of equilibrium, the needle will take its mean position, subject only to those diurnal changes which arise from the action of solar heat. But when the magnetic matter is exposed to the electrical agents which exercise so powerful an influence on the regions of the clouds, when the ferruginous matter, and the other metallic vapours which accompany it, are rendered luminous by the transmission of the electric fluid, and when the the magnetic matter has its induced magnetism either diminished or increased by this cause, the resultant of the forces which act upon the needle must be changed, and motions regular and irregular, easterly and westerly, or in any given direction, communicated to a needle freely suspended by its centre of gravity. A local displacement of the magnetic matter, by the various causes which are constantly disturbing our atmosphere, or local and limited electric action, must necessarily affect such a needle; but it is easy to conceive that those local and limited actions may be such as to balance each other, and not change the direction of the resultant force which acts either upon a horizontal or a dipping needle. Nay, it is easy to conceive a general diffusion of electricity, capable of illuminating the magnetic matter with such perfect equality in all magnetic azimuths, without at all affecting any needle, however balanced or suspended; because the electrical influence may not change the direction of the resulting forces which give the needle its mean direction. In such a case, however, it is probable that the magnetic intensity might be increased or diminished during the existence of such an electric state of the magnetic matter. We cannot, therefore, adopt the opinion of Mr Christie, *that every aurora must disturb the magnetic needle;* and we admit only the observed fact, that there are auroras which disturb, and auroras which do not disturb, the needle.

In order to explain more fully our views on this subject, let us suppose our magnetic atmosphere to be undisturbed by any cause, and that the needle in every magnetic meridian rests in a state of perfect equilibrium in its mean position. Let us now suppose that the magnetic atmosphere is disturbed in east longitude 90° and latitude 0°, either by a change of temperature, or by electric action, or by any cause which displaces the magnetic matter from that meridian, or accumulates it there. Such a change must necessarily affect the horizontal magnetic needle in all places to the east and west of it; but it will not affect the horizontal needle in the meridian where it takes place, or in the opposite meridian, as the resultant of the magnetic forces, though they may be changed in intensity, will not be changed in direction. In like manner, if various discharges take place simultaneously or successively, there will be certain places where the direction of the resultant forces is not changed, and other places where the change of direction is a maximum. An universally suspended needle, however, will have its direction always changed, unless when the disturbing cause is in the direction of its axis, or in a plane perpendicular to that axis. Hence, then, it is easy to understand (nay, the fact is a necessary result of our hypothesis) why there are auroras which disturb and auroras which do not disturb the needle, why distant auroras affect it when nearer ones do not, and why the needle is in a shivering or constantly oscillating state during auroras in which the places where the magnetic atmosphere is disturbed are constantly changing. In the same manner, we may account for the influence on the needle, observed by Sir Everard Home and Captain Back, during the prevalence of a thunder storm, while the electricity of the atmosphere destroys by its action the magnetic equilibrium, when this action is not compensated by an equal one on the opposite side of the magnetic meridian. When such a compensation takes place, the needle will not deviate from its mean position, though the number of its vibrations in a given time may be altered.

Among the other causes which have a tendency to disturb the magnetic needle, we may enumerate earthquakes and volcanic eruptions, all of which are accompanied in general with electrical phenomena. In 1767, Daniel Bernoulli observed the dip of the needle to diminish half a degree during an earthquake; and De la Torre observed changes of several degrees in the variation of the needle during an eruption of Vesuvius.

SECT. II.—*On the Dip or Inclination of the Needle.*

Dip of the needle.

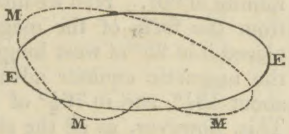
The dip or the inclination of the needle is, as we have already had occasion to observe, the angle which a well-balanced needle forms with the horizon after it is rendered magnetic, and when it has the power of free motion in the plane of the magnetic meridian, as shown in Plate CCCXXV. fig. 9, where NS is the needle balanced on a horizontal axis, at right angles to its length.

The dip of the needle, like the variation, has different values in different parts of the globe; generally speaking, being nothing, or horizontal, near the equator, and 90°, or perpendicular to the horizon, at the magnetic poles. The line passing round the globe near its equator, in every part of which the dip is nothing, is called the *magnetic equator*, which is a very irregular line, crossing the equator at *four* points, as shown in the annexed figure, where the black line E E is the real equator, and the dotted line MMM the magnetic equator, which is seen to cross the other at four points, in place of two.

---

[1] *Narrative of the Arctic Land Expedition*, &c. p. 41, 42.

Fig. 49.



The general inclination of the magnetic to the terrestrial equator is about 12°, its principal intersections or nodes being placed in 113° 14′ west longitude and 66° 46′ east longitude from Greenwich; and it is a tolerably regular line throughout one half of its circumference in the Atlantic and Indian Oceans. In discussing the observations made by Cook and others in the South Sea, M. Biot has shown that the above elements are incorrect everywhere beyond the western node, between 115° and 270° west longitude; and he concludes that between 256° and 158° 50′ of west longitude it again cuts the terrestrial equator at least once, which renders it necessary that it cut it another time near the east coast of Asia, provided it is found in the Atlantic Ocean or the south latitude. Hence there will be at least three nodes, and perhaps four, as shown in the preceding figure. This singular inflexion of the magnetic equator in the South Sea has been confirmed by the more recent observations of M. Freycinet.

The exact position of these nodes, and the true form of the magnetic equator, have been determined with great care by M. Morlet and M. Hansteen. There are some slight differences between their results, which have been pointed out by M. Arago, in the following excellent summary of the results of their inquiry. Both Morlet and Hansteen place the magnetic equator wholly to the south of the terrestrial equator, between Africa and America; its greatest southern latitude being at 25°, one node is in Africa, in about 22° of east longitude, or in 18° according to Morlet. In setting out towards the east from this node, which is nearly in the centre of that part of the African continent, the magnetic equator advances rapidly to the north of the terrestrial equator, quits Africa a little to the south of Cape Guardafui, and in the Arabian Sea it attains its most northerly latitude of about 12°, in 62° of east longitude. Between this meridian and 174° east, the magnetic equator is constantly to the north of the equinoctial line. It cuts the Indian peninsula a little to the north of Cape Comorin, traverses the Gulf of Bengal, making a slight advance to the equinoctial, from which it is only 8° distant at the entry of the Gulf of Siam. It then re-ascends a little to the north, almost touches the north point of Borneo, traverses the isle of Paragua, the strait which separates the most southern of the Philippines from the isle of Mindanao, and under the meridian of Naigiou it again reaches the north latitude of 9°. From this point it traverses the archipelago of the Caroline Islands, and descends rapidly to the equinoctial line, which it cuts, according to Morlet, in 174°, and according to Hansteen in 187°, of east longitude. There is much less uncertainty respecting the position of a second node, also situated in the Pacific Ocean. Its west longitude ought to be about 120°; but while M. Morlet's inquiries lead him to conclude that the magnetic equator merely touches the equinoctial at that point, and then bends again to the south, M. Hansteen makes it cross the line into the northern hemisphere, and continue there through an extent of 15° of longitude, and then return southward, and cross the equinoctial again in about 108° of west longitude, or 23° from the west coast of America. This discrepancy between the deductions of Morlet and Hansteen is, after all, very trivial; for, in the case just mentioned, the magnetic equator does not go more than 1½° to the north of the equinoctial; and, in general, the magnetic equator of Morlet differs in no part so much as 2° in latitude from that of Hansteen.

The magnetic equator thus traced over the globe has a motion from east to west, in so far as can be determined by direct observations on the position of its nodes. The two nodes of Hansteen, corresponding to the tangent node of Morlet, are divided between 108° and 126° of west longitude. In 1819, M. Freycinet found, on board the Uranie, that this node was in 132° of longitude; and Captain Sabine found that the node in Africa, which was far from the coast in 1780, had advanced from east to west even to the Atlantic Ocean. M. Morlet had indicated, with some distrust, this motion of the magnetic equator; and he considered it probable that its form and position regulated the direction of the annual variations of the needle. He found that the dip of the needle diminished wherever the motion of the equator tended to diminish the magnetic latitude, and that it increased, on the contrary, wherever the magnetic latitude was increased; a result which was confirmed by future observations.

Much light has been thrown on the subject of terrestrial magnetism, but particularly on the form and motion of the magnetic equator, by the observations of Captain Duperrey, made on board the Coquille, in the years 1822–1825. This vessel crossed the magnetic equator six times, and M. Duperrey was able to determine directly two of its points, situated in the Atlantic Ocean. On the chart of M. Morlet, and in that of Hansteen, the latitudes of those parts which correspond to the same longitudes are greater by 1° 43′ and 1° 50′; and hence M. Arago has concluded that the magnetic equator has approached the terrestrial equator by the same quantities. In the South Sea, near the coast of America, M. Duperrey has determined two points of the magnetic equator. On the charts of Morlet and Hansteen the latitudes of these points is about a degree smaller, but the difference is in a direction contrary to that which was found in the Atlantic Ocean; from which it follows, that, near the coast of Peru, the magnetic equator has removed from the equinoctial line.

In discussing the magnetic observations made on board the Coquille, M. Duperrey has traced the form of the magnetic equator with an unexpected degree of accuracy; employing the formula of Barlow, which makes the tangent of the magnetic latitude equal to half the tangent of the dip, and making one only of dips which do not exceed 30°. Having obtained the magnetic latitudes of the places where the observations were made, he deduces, both from these and from the variation of the needle at the same place, the changes in longitude and latitude, which, being combined with the geographical positions of the stations, give him the coordinates of the corresponding points of the magnetic equator. By means of this method, and relying only on his own observations, he has traced a portion of this curve through an extent of 247° of longitude, comprehending the Atlantic Ocean, a part of South America, the great equinoctial ocean, and the Asiatic archipelago, as far as the western extremity of the island of Borneo. In prolonging the magnetic equator to the east, he has used the observations of Captain Sabine in 1822, made in the island of St Thomas, in the Gulf of Guinea. Between the west of Borneo and the north of Ceylon, he availed himself of the observations made in 1827, by M. de Blosseville, in the Chevrette. Adopting Captain Sabine's determination of one of the nodes of the magnetic equator, which he places 3° 20′ to the east of the meridian of Paris, not far from the west coast of Africa, M. Duperrey shows that this equator, after resting at this node, rises to the north, traverses Africa, and reaches probably the fifteenth degree of north latitude, in the Red Sea (as appears from an observation made by Pantin in the isle of Socotra in 1776). It then descends a little to the south, to join a point in it fixed by M. Blosseville in the north of Ceylon. From these facts it appears, *that the magnetic equator will meet the equinoctial line only in two points, which are diametrically opposite, the one situated in the Atlantic Ocean, and the other in the great ocean nearly in the plane of the meridian of Paris. When this equator meets only some scattered islands, it recedes only a little from the equinoctial line. When the islands are more numerous, it recedes farther; and it reaches its maximum deviation in both hemispheres only in the two great continents which it traverses. He found also, that between the northern and southern halves of the magnetic equator, there is a symmetry very remarkable, and much more perfect than had been previously believed.* These results are laid down by M. Duperrey in a chart of the equatorial regions, published in the *Ann. de Chimie* for 1830.

The dip of the needle increases on each side of the magnetic equator, and Hansteen has projected the lines of equal dip in his chart already referred to. These lines are nearly parallel to the magnetic equator, till we reach 60° of north latitude, and they then begin to bend round the American magnetic pole, which Commander Ross found to be situated in north latitude 70° 5′ 17″, and west longitude 96° 45 48″, the needle having at this point, in Boothia Felix, lost wholly its directive power, and the dip being 89° 59′, within a minute of 90°. Had we inferred the position of the needle from the form of the magnetic equator, we should have placed it in 25° of west longitude, viz. the meridian in which the magnetic equator advances farthest to the south, or about 13½°, and in 76½° of north latitude, or 90° — 13½°. This, however, as all the arctic observations prove, is not the case; and we are led by the phenomena of the dip, as well as by those of the variation in different points of the globe, to conclude that every place has its own magnetic axis, with its own pole and its own equator, as already stated by Mr Barlow.

The following table contains the best observations on the dip of the needle, as collected by Professor Hansteen:—

On the Progressive Change in the Dip of the Needle.

The dip of the needle, like the variation, undergoes a continual change, increasing in some parts of the world, and diminishing in others. The following table shows the change which has taken place in the dip at Paris from 1671 down to 1829.

Year.	Dip.	Year.	Dip.
1671	75° 0′	1818	68° 35′
1754	72 15	1819	68 25
1776	72 25	1820	68 20
1780	71 48	1821	68 14
1791	70 52	1822	68 11
1798	69 51	1823	68 8
1806	69 12	1824	68 7
1810	68 50	1825	68 0
1814	68 36	1826	68 0
1816	68 40	1829	67 41 Arago.
1817	68 38		

The following table shows the changes of the dip at London since 1720.

Year.	Observed.		Computed.
1720,	74° 42′	Graham.	76° 27′
1773,	72 19	Heberden.	73 40
1780,	72 8	Gilpin.	73 18
1790,	71 53	Ditto.	72 39
1800,	70 35	Ditto.	71 58
1810,			71 15
1818,	70 34	Kater.	70 34
1821,	70 3	Sabine.	
1828,	69 47	Ditto.	69 43
1830,	69 38	Kater.	
1833,			69 21

The last column in the table was calculated by Professor Barlow, by his formula, 2 cotan. πL = tan. dip, or that the tangent of the dip is equal to double the tangent of the magnetic latitude.

---

[1] An island in the Caspian Sea.

The progressive variation in the dip of the needle is, as M. Humboldt has shown, the necessary consequence of a change in the magnetic latitude, arising from the motion of the nodes of the magnetic equator modified by the form of this curve; and M. Morlet has applied the same principle to account for the variations of the dip in different parts of the globe.

Humboldt and Arago have endeavoured to deduce the annual diminution of the dip occasioned by the motion of the magnetic equator. By comparing the observations of 1778 and 1810 for Paris, the annual diminution was about 5′, whereas, from those of 1820 and 1825, it appears to be only 3′·3. The observations at Turin from 1805 to 1826 give 3′·5, and those of Florence 3′·3.

Besides the progressive variation of the dip, Hansteen has found, from a series of observations made with a dipping needle by Dollond, that the dip during the summer was about fifteen minutes greater than during the winter, and about four or five minutes greater in the forenoon than in the afternoon.

SECT. III.—*On the Intensity of Terrestrial Magnetism.*

Intensity of terrestrial magnetism.

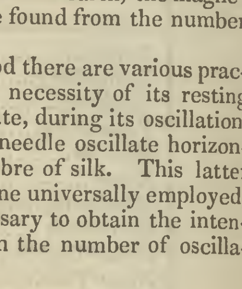
The determination of the intensity of the earth's magnetism at different points of its surface, and of the changes which it undergoes either progressively or at different times of the day and different seasons of the year, has become one of the most important practical problems connected with the physical condition of the globe.

The method of determining this important element by the number of oscillations of the needle was first suggested by Graham, and brought to perfection by Coulomb, Humboldt, and others. If a needle whose axis of suspension passes through its centre of gravity, and which has its north polar and south polar magnetism equal, and similarly distributed, is made to vibrate by turning it from its position, and allowing it to receive that position by a series of oscillations, it is obvious that the earth's magnetism acts with equal force on each half, and that both these forces tend to draw the needle into the magnetic meridian. The greater the magnetic force, the more quickly will the needle oscillate and recover its primitive position. The needle is, in short, in the same circumstances as a pendulum, oscillating by the action of gravity; and, as in this case, the forces are as the squares of the number of oscillations made in the same time.

Let us now suppose, to take the simplest case, that we make the dipping-needle oscillate in the plane of the magnetic meridian, round the line of the dip, and that when the experiment is performed at the equator, the number in a second is 24, while in another place it is 25; then the intensities of the magnetic force at these places is as 25^2 to 24^2, or as 625 to 576, or as 1·085 to 1·000. By carrying the same needle to different parts of the earth, the magnetic intensity at these places will be found from the number of its oscillations.

In the application of this method there are various practical difficulties, particularly the necessity of its resting upon knobs, edges of steel, or agate, during its oscillation, which do not exist if we make a needle oscillate horizontally when suspended by a fine fibre of silk. This latter method has, therefore, been the one universally employed, though a little calculation is necessary to obtain the intensity of terrestrial magnetism from the number of oscillations which are performed.

Fig. 50.



Let NS be a magnetic needle suspended horizontally by a fibre of silk P, and let NC be the line of the dip, or ANC = D the dip itself. Then if F is the force of terrestrial magnetism acting upon the oscillating needle, and tending to bring it to rest, we may decompose this force into two, viz. one, NB, acting in a vertical direction, and which, being counteracted by the suspended force, has no tendency to affect the needle; and the other, NA, acting horizontally, and tending to direct the needle, and cause it to oscillate. This force NA is the cosine of ANC, the dip D. Hence the force NA will be equal to F × cos. D. For any other place where the magnetic intensity is F′ and the dip D′, the effective force will be F′ × cos. D′; and if we call N the number of oscillations made in a second at the first place, and N the number at the second, we shall have $F \times \cos. D : F' \times \cos. D' = N^2 : N^2$, and the ratio of the magnetic intensities at the two places, or $\frac{F}{F'} = \frac{N^2 \cos. D}{N'^2 \cos. D'}$.

In this way observations on the magnetic intensity have been made in almost every part of the world, as shown in the following table, drawn up by Professor Hansteen, and containing observations made principally by himself and his friends. The third column contains the number of seconds in which 300 vibrations of the needle are performed.

The principal intensities computed from these observations will be found in our table of the dip given above.

It is obvious from these data that the magnetic intensity increases from the equator to the poles, and the law of variation is shown in the following table :

Dip of the Needle.	Magnetic Intensity.
0°	1·0
24	1·1
45	1·2
64	1·3
73	1·4
76⅔	1·5
81	1·6
86	1·7

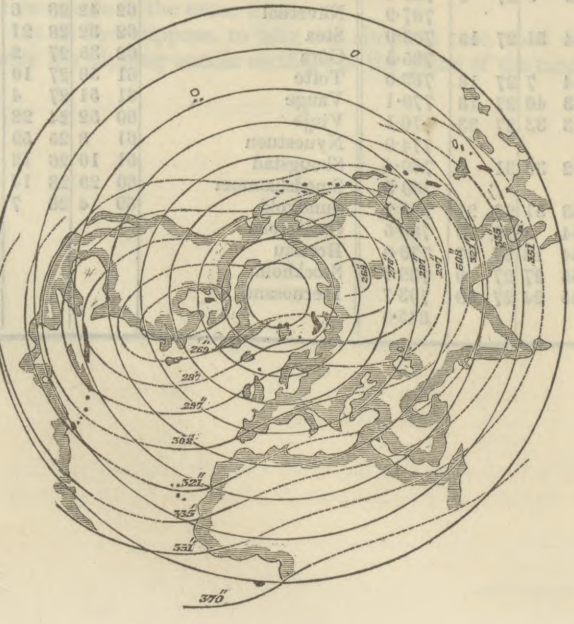
M. Hansteen has projected upon a map of the globe the lines passing through all the places in which the intensity has the same value. These lines he calls *isodynamic lines*, or those of *equal force*, and they are, generally speaking, nearly parallel to each other, and to the lines of equal dip.

Hansteen's observations in Siberia.

Many valuable observations on the intensity of the earth's magnetism were made during the numerous arctic expeditions which were sent out by the British government; but Professor Hansteen being extremely desirous of establishing, by direct observations of his own, the existence of the secondary magnetic pole, which he believed existed in Siberia, set out for this purpose, at the expense of the Norwegian Storthing, and with every encouragement and assistance from the Russian government. The results of this expedition exceeded his most sanguine expectations. The Russian Academy of Sciences have, in consequence of Professor Hansteen's scientific journey, been induced to take a new interest in the subject of terrestrial magnetism, which exhibits such interesting features throughout the Russian empire; and the Russian government has established regular observatories in different parts of its vast dominions, for making magnetical experiments. The Russian empire is actually traversed by *two* lines of no variation, and it is proposed to determine with great precision, every ten years, the exact position of these two lines. Near the first of them, which traverses European Russia, Petersburg, Moscow, and Kasan, are situated; and near the second, which passes through Siberia, is situated Kiachta and Nizni-Oudinsk.

The principal observations made by Hansteen in Siberia have been laid down in a map of the northern hemisphere by Captain Sabine, along with other observations made by himself and Humboldt. In this map, of which the prefixed figure is a copy, it is exceedingly interesting to observe the isodynamic lines surrounding the two northern magnetic poles, and forming a series of returning curves similar to lemniscates, and which may be calculated by the formulæ of Sir David Brewster, already given in the History of Magnetism.

Fig. 51.



In this map the *American* pole is situated nearly in 60° of N. lat. and 80° of W. long.; and the *Asiatic* pole in 60° N. lat. and 100° of E. long. The black lines pass through the places where the magnetic intensity was observed to be equal, and the dotted parts of the same curves indicate the probable direction of the lines where observations have not yet been made. The lines round the American pole are laid down principally from Captain Sabine's observations, and those round the Asiatic pole from the recent observations of Hansteen. The following is the account given of the different isodynamical lines in the figure, by Captain Sabine.

The *first* curve, or that nearest the magnetic poles, is that in which a magnetic needle which performs *n* oscillations in 300″ in London, performs the same number in 269″ round the Asiatic pole. This curve contains a smaller space than the corresponding curve round the American pole, which proves the inferior activity of the former pole. Hansteen traced the south part of this curve below lat. 60°, from the river Jenisei to the 115th degree of W. long., that is, 25° beyond the Jenisei, and to lat. 60°, where it takes a direction almost due north.

The *second* curve, or that in which the same number *n* oscillations are performed in 278 seconds, goes round both the American and Asiatic poles, including both within its area. It passes to the north-west of Melville Island, and to the north-east of some stations on the west coast of Greenland; and it cuts the American coast between the Havannah and New York. Dr Erman, who accompanied Hansteen into Siberia, traced the same curve from the embouchure of the Oby, in N. lat. 68°, and E. long. 70°, following the direction of the river Mina as far as 60° N. lat. The curve here gradually bends to the east, and after passing between Tobolsk and Narym, it was again detected by M. Hansteen at Kainsk, a few degrees to the south of Lake Baikal.

The *third* curve, or that in which *n* oscillations are performed in 287″, is drawn on the American side, from observations made at the Havannah, at the Pendulum Isle on the east coast of Greenland, in N. lat. 74° 5′, and between Spitzbergen and Hammerfest, near the North Cape. This curve, according to Hansteen, enters Europe between Archangel and Nova Zembla; and he met with it again between Moscow and Tobolsk, at 56½° of E. long. and 57½° of N. lat.

The *fourth* curve, or that in which *n* oscillations are performed in 297 seconds, passes near Jamaica, where the oscillations were performed in 294 seconds, and, after traversing the north of Britain, it enters Norway to the south of Bergen. Advancing eastward, it passes between Stockholm and Torneo, and thence by St Petersburg and Moscow.

The observations of Professor Hansteen do not extend farther south than these lines, and therefore Captain Sabine has laid down in the map the lines in which *n* oscillations are performed in 308, 321, 335, 351, and 370 seconds, from his own observations and those of Humboldt. The lowest number of seconds in which *n* oscillations are performed is at the magnetic poles, where it is nearly 262 or 263, and the greatest, 370, the time in which they are performed at the equator.

We have stated that the isodynamical lines are nearly parallel to those of equal dip. This is the case in Scotland; but towards the east, in Norway and Sweden, the lines of equal intensity bend more to the north, and cut the former; and also, under the same line of equal dip, the intensity is weaker to the east than to the west. Hence M. Hansteen has found that the pole of the lines of equal dip lies in 71° of lat., and 102° of long., while the pole of intensity is in 56° of lat., and 80° of long. west of Paris. The first of these determinations coincides very nearly with the pole of Commander Ross, where the dip was 90°. The latest observations made during the arctic expeditions from England, and also those by Hansteen and Erman in Siberia, prove beyond a doubt the accuracy of the earlier conclusion of Hansteen, that the lines of equal intensity and equal dip are not parallel. Humboldt discovered the node of the magnetic equator with the isodynamical curve in 7° of S. lat., and 81° of long. west of Paris. He traced this last line to the west of the Cordilleras of the Andes, and along the coast of Peru, towards Kasma and Fluormay, even to the 10th degree of S. lat. M. Adolphus Erman found in Siberia, that the isodynamic line, where the intensity is 1·60 (that of the equator being 1·00), directs itself also from north to south with a slight inclination to the south-east. He observed this line *cut almost at right angles the curves of equal dip*, and then descend from the north-north-west to the south-south-east, from Ochotsk, near the mouths of the Oby, to Tomsk. M. Humboldt is of opinion that the isodynamical line and the Peruvian node of the magnetic equator have been carried, since his voyage, from east to west; and he informs us that M. A. Erman, in the 135th degree of long. west of Paris, and in the magnetic equator, found that the intensity of the magnetic forces was sensibly the same as he had found them twenty-six years before on the magnetic equator in Peru.

As the intensity of terrestrial magnetism at different places is not a function of the dip at these places, and the isodynamic lines are not parallel to those of equal dip, it is probable that different points of the equator have not the same magnetic intensity. "Having carried," says Humboldt, "the same needle or needles compared with them, from Paris to Mexico, to the magnetic equator in Peru, to Berlin, to Petersburg, to the shores of the Caspian, and to the north of Asia, I have expressed the magnetic intensities at these places, by taking for unity the intensity which I find on the magnetic equator in Peru, or rather in the intersection of this equator with the isodynamical line of minimum intensity. On this supposition, I find for Paris 1·3482, for Milan 1·3121, for Naples 1·2745. The very valuable observations of M. Rossel, at Surabaya in Java, and those of Captain Sabine near St Thomas, 5° north of the equator, indicate that the magnetic intensity is less on the magnetic equator near the west coast of Africa (long. 40. 24. W.), and in the great Italian archipelago, than in the portion of the magnetic equator which crosses Peru. Besides, M. A. Erman has observed, that on the east coasts of South America the intensities are much weaker at the same distances from the south terrestrial pole than on the west coasts. The intensity 1·00, found to the west of the new continent, on the magnetic equator in the South Sea, in 135° of west longitude, and 1° 55′ of south latitude, shows itself on the coasts of Brazil towards the 38th degree of south latitude, while the dip is there even more than 37° south. It appears to me more probable that the minimum intensity at the surface of the earth is to the maximum, not as 1 to 1·6 or 2, as has been supposed, but even much beyond the ratio of 1 to 2·6."

Observations are yet wanting to determine in what manner the intensity varies with the height. Humboldt is of opinion that it decreases, thus confirming the deductions of Kupffer.

By combining all the observations of intensity from 179° to 183°, M. Hansteen has drawn the conclusion, *that the total magnetic intensity is smaller in the southern than in the northern hemisphere.* M. Duperrey has confirmed this result. According to the investigations of Biot, the natural magnetic intensity, or I, is $= 2A.\sqrt{\frac{1}{4 - 3\sin^2\delta}}$, and that of the horizontal needle $= 2A\sqrt{\frac{1}{3 + \sec^2\delta}}$, δ being the dip; but these formulæ presuppose that the earth is perfectly homogeneous, and of course they cannot be verified by insulated observations. M. Duperrey has therefore been obliged, in order to bring all these observations into this state, to take the mean intensity of the terrestrial equator and of each of the parallels of the globe, and to multiply the circumference of each curve by its intensity in order to have the total intensity, and then to take the mean of the total intensities of the corresponding parallels in each hemisphere. In this manner he obtained all the points of the curve which represents the law of the increase of the magnetic forces from observation. The curve thus traced, when compared with that which is calculated by the formula of M. Biot, does not deviate from it above 0·015 of the intensity, supposing the intensity at the magnetic equator in Peru to be 1. He has found also that the surface of the north magnetic hemisphere is to that of the south one in the ratio of 1·0000 to 1·0152, a ratio which is the same as that of the total intensity of the south terrestrial hemisphere to the total intensity of the north terrestrial hemisphere; and he hence concludes, that *the surfaces of the two magnetic hemispheres are proportional to the intensities of the two terrestrial hemispheres.*

On the Monthly and Daily Change of Intensity.

Monthly and daily changes of intensity.

The magnetic intensity, like the other elements of terrestrial magnetism, suffers monthly and diurnal changes. By means of the vibrations of a needle delicately suspended, M. Hansteen found that the *minimum* of the daily change of intensity is between ten and eleven in the forenoon, and the *maximum* between four and seven in the afternoon in May, and about seven in June. The intensity is a maximum in December, and a minimum in June. The greatest monthly change in the intensity is a maximum in the months of December and June, about the time when the earth is in its perihelion and aphelion. It is a minimum near the equinoxes, or when the earth is at its mean distance from the sun. The greatest daily change is least in the winter and greatest in the summer, the greatest difference of the annual change of intensity is 0·0359. M. Hansteen has likewise found, that the magnetic intensity is diminishing in Europe, and that the decrease is greater in the northern and eastern, than in the southern and western parts, an effect which he conceives to be produced by the motion of the Siberian pole towards the east. At port Bowen, Captain Parry observed an augmentation of the magnetic intensity to take place from the morning till the afternoon, and a diminution of it from the afternoon till the morning. These results of Hansteen have been confirmed by Mr Christie,[1] who has shown that the terrestrial magnetic intensity is a minimum between ten and eleven o'clock in the morning, the time nearly when the sun is in the magnetic meridian; that it increases from this time until between nine and ten o'clock in the evening, after which it decreases, and continues decreasing during the morning, till it reaches its minimum between ten and eleven. These results were deduced from observations made in May, *within doors,* to determine the positions of the points of equilibrium at which a magnetic needle was retained at different hours during the day, by the joint action of two bar-magnets, and of terrestrial magnetism reduced to their true positions at the standard temperature (60°) of the magnets. As this change in the position of these points was produced by the change in the magnetic intensity, Mr Christie thus obtained accurate measures of the last of these elements by means of the formula

---

[1] *Phil. Trans.* 1825, p. 49–51.

$$M - F\,(\cdot 004690814 + \cdot 000829329 \cos.^2 \varphi) = 0,$$

in which M is the horizontal part of the terrestrial magnetic force, acting on the north arm of the needle in the line of the dip, F the force with which a pole of the needle is repelled from a pole of the same name of either magnet, or attracted towards that of a contrary name at the unity of distance, and φ the angle which the axis of the needle makes with the meridian, or the azimuth of the point of equilibrium.

Mr Christie repeated his observations in *the open air* in June, and from these it appears that the minimum intensity happened nearly at the time the sun passed the magnetic meridian, and rather later than in May, which was also the case with the time of the sun's passage over the meridian. The intensity increased until about six o'clock in the afternoon, after which it appears to have decreased during the evening, and to have been decreasing from an early hour in the morning. Mr Christie has given the following interesting view of Hansteen's results and his own.

Intensity deduced from Hansteen's Observations in 1820.			Intensity deduced from Mr Christie's Observations in 1823.		
Time.	May.	June.	Time.	May.	June.
8 *h.* 0′ A. M.	1·00034	1·00010	7 *h.* 30′	1·00114	1·00061
10 30	1·00000	1·00000	10 30	1·00000	1·00000
4 0 P. M.	1·00299	1·00251	4 30	1·00175	1·00223
7 0	1·00294	1·00304	7 30	1·00220	1·00239
10 30	1.00191	1·00267	9 30	1·00231	1·00209

The principal difference between these results is, that in Mr Christie's observations the intensity seems to diminish more rapidly in the morning, and increase more slowly in the afternoon, than it does in those of Hansteen.

The following table shows the horizontal magnetic intensity at Göttingen, as determined by Professor Gauss, in different months of 1832, with great accuracy.

1832.	Horizontal Intensity.	1832.	Horizontal Intensity.
May 21.	1·7820	July 25, 26.	1·7845
„ 24.	1·7694	Sept. 9.	1·7764
June 4.	1·7713	„ 18.	1·7821
„ 24–28.	1·7625	„ 27.	1·7965
July 23, 24.	1·7826	Oct. 15.	1·7860

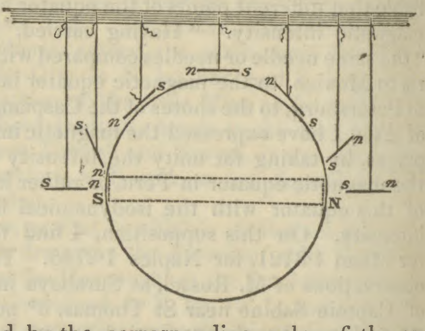
In order to obtain from these numbers the absolute magnetic intensity, to compare them with the results in Hansteen's table, they must be multiplied by the secant of 68° 22′ 22″, the dip at Göttingen on the 23d June 1832.

SECT. IV.—*On the Nature and Causes of the Earth's Magnetism.*

Nature and causes of the earth's magnetism.

The phenomena described in the preceding sections afford abundant evidence that the earth is in some way or other magnetic; but what is the nature of its magnetic condition, or from what cause it derives its origin, are points which it is not easy to determine. The earliest and the most natural supposition is that of Dr Gilbert, that the earth contains within itself a powerful magnet, lying in a position which nearly coincides with its axis of rotation. In this case, the pole of this magnet, which acts in our northern hemisphere, must have south polar magnetism, as it attracts the north pole of the needle; while the pole in the southern hemisphere must have north polar magnetism, as it attracts the south pole of the needle. That this hypothesis would, generally speaking, represent the ordinary phenomena of terrestrial magnetism, may be easily shown by placing a bar-magnet within a terrestrial globe, and observing the phenomena exhibited by a small needle suspended at its centre of gravity by a fine thread or fibre. As the magnet is placed out of the axis of rotation, the needle in the northern hemisphere will always point to the north end of the enclosed magnet, exhibiting all the phenomena of the variation of the needle, as usually observed. The general phenomena of the dip will also be exhibited, as shown in the annexed figure, where NS is the direction of the enclosed magnet, shown by dotted lines, S being the northern magnetic pole, and N the southern, and *ns*, *ns*, small needles suspended by fibres *f, f, f.* The needle has no dip at the equator, because each pole is equally attracted by the corresponding poles of the enclosed magnet, and at the poles S, N the dip is 90°, as observed at the northern magnetic pole by Commander Ross. At latitudes intermediate between the magnetic equator and the magnetic poles, the dip has an intermediate value.

Fig. 52.



In the same manner as a common bar-magnet communicates magnetism to a piece of soft iron held near it, the supposed magnet in the earth communicates magnetism to a soft iron bar held in the magnetic meridian, and parallel to the dipping-needle, which in this country is not far from a vertical position. The soft iron is temporarily a magnet, exactly like the soft bar in the presence of a real magnet, and possesses the very same properties.

In the progress of discovery, however, it has been found, that the phenomena of the dip and the variation are more complex than this hypothesis will allow us to suppose; and in measuring the magnetic intensity in Siberia, Hansteen has proved that there is another magnetic pole in that country, which regulates the magnetic phenomena. In order to account for these, we must therefore suppose another magnet passing through the globe in the direction

Terrestrial Magnetism.

Cause of the earth's magnetism.

of a diameter whose pole coincides with the Siberian magnetic pole. But even this addition to the hypothesis of Gilbert will not explain the phenomena, unless we resort to the absurd assumption of Halley, who gives rotatory movements to magnetic spheres placed in the interior of the globe.

A more sober and philosophical hypothesis is one which has been long gaining ground, and which recent discoveries have rendered still more probable. According to this hypothesis, the magnetism of the earth is not that of a magnet, but that of a sphere or spherical shell of iron on which magnetism is induced. The difference between these two magnetic states is very great. In regular magnets the centres of action are placed at their extremities or poles; but in masses of iron, either hollow or solid, either regular or irregular, the centres of action are always coincident with the centre of attraction of the surface of the mass. When the observations on the variation and dip of the needle became numerous and accurate, philosophers soon perceived that they could not be explained by the action of two magnetic poles at a distance from each other. M. Biot had the merit of first viewing the subject in this light, and he at length came to the conclusion, that the nearer the poles were taken to each other, the greater was the agreement between the computed and observed results; and by assuming the two centres as indefinitely near to each other in the centre of the earth, the coincidence between observation and calculation was as great as could be expected. Now it is a remarkable fact, that Mr Barlow discovered, as we have already seen, that such a coincidence in the centre of action actually takes place in all bodies which are magnetic by induction, such as iron spheres or shells; and he has applied this principle to account for the various phenomena of the dip and variation of the needle. Almost all the philosophers who have since investigated the subject have adopted this idea; and the only difficulty which attaches to it is, where to find the cause by which the earth's magnetism is induced. The following speculations on this curious subject are hazarded by M. Hansteen, in his work on the magnetism of the earth.

Hansteen.

"For these reasons, it appears most natural to seek their origin in the sun, the source of all living activity; and our conjecture gains probability from the preceding remarks on the daily oscillations of the needle. Upon this principle, the sun may be conceived as possessing one or more magnetic axes, which, by distributing the force, occasion a magnetic difference in the earth, in the moon, and all those planets whose internal structure admits of such a difference. Yet, allowing all this, the main difficulty seems not to be overcome, but merely removed from the eyes to a greater distance; for the question may still be asked with equal justice, *whence did the sun acquire its magnetic force?* And if from the sun we have recourse to a central sun, and from that again to a general magnetic direction throughout the universe, having the milky-way for its equator, we but lengthen an unrestricted chain, every link of which hangs on the preceding link, no one of them on a point of support. All things considered, the following mode of representing the subject appears to me most plausible. If a single globe were left to move alone freely in the immensity of space, the opposite forces existing in its material structure would soon arrive at an equilibrium conformable to their nature, if they were not so at first, and all activity would soon come to an end. But if we imagine another globe to be introduced, a mutual relation will arise between the two; and one of its results will be a reciprocal tendency to unite, which is designated, and sometimes thought to be explained, by the merely descriptive word attraction. Now, would this tendency be the only consequence of that relation? Is it not more likely that the fundamental forces, being driven from their state of indifference or rest, would exhibit their energy in all possible directions, giving rise to all kinds of contrary action? The electric force is excited, not by friction alone, but also by contact, and probably also, though in smaller degrees, by the mutual action of two bodies at a distance; for contact is nothing but the smallest possible distance, and that, moreover, only for a few small particles. Is it not conceivable that magnetic force may likewise originate in a similar manner? When the natural philosopher and the mathematician pay regard to no other effect of the reciprocal relation between two bodies at a distance, except the tendency to unite, they proceed logically, if their investigations require nothing more than a moving power; but should it be maintained that no other energy *can* be developed between two such bodies, the assertion will need proof, and the proof will be hard to find.

Terrestrial Magnetism.

Cause of the earth's magnetism.

"I reckon it possible, therefore, that, by means of the mutual relations subsisting between the sun and all the planets, as well as between the latter and their satellites, a magnetic action may be excited in every one of those globes whose material structure admits of it, in a direction depending on the position of the rotatory axes with regard to the plane of the orbit. Each of the planets might thus give rise to a particular magnetic axis in the sun; but as their orbits make only small angles with the sun's equator and each other, these magnetic axes would, perhaps, on the whole, correspond with the several rotatory axes. Such planets as have no moons would, on this principle, have but one magnetic axis; the rest would, in all cases, have one axis more than they have moons, if those different axes, by reason of the small angles which the orbits of their several moons form with each other, did not combine into a single axis. The conical motions by which the rotatory axes of the planets are carried round the pole of the ecliptic (the precession in the earth), joined to the revolving motion of the orbits about the sun's equator (which occasions the present diminution in the obliquity of the ecliptic), might perhaps, in this case, account for the change of position in the magnetic axis. It would greatly strengthen this hypothesis, if the above great magnetic period, after the lapse of which both axes again assume the same position, should in fact be found to coincide with the period of the precession, which, however, seems a little doubtful."

Such was the state of speculation on this part of the subject when Hansteen published his work on the magnetism of the earth. The poles of our globe were then regarded as the coldest parts on its surface; and no conjecture even had been hazarded regarding the connection between the phenomena of terrestrial temperature and terrestrial magnetism, till Sir David Brewster proved, from an immense number of meteorological observations, that there were in our northern hemisphere two poles of maximum cold; that these poles coincided with the magnetic poles; that the circle of maximum heat, like the magnetic equator, did not coincide with the equinoctial line; that the isothermal lines, and the lines of equal magnetic intensity, had the same general form surrounding and enclosing the magnetic poles and those of maximum cold; and that, by the same formula, *mutatis mutandis*, we could calculate the temperature and the magnetic intensity of any point of the globe. These views we have referred to more fully in the history of magnetism.

The monthly and daily changes in the intensity of terrestrial magnetism, and in the dip and variation of the needle, had led Canton and others to ascribe these changes to the action of the sun; and Captain Duperrey, in his paper on the magnetic equator, has ascertained, that the points of this great circle, or those where the magnetic intensity is a minimum, are also the warmest points of each meridian, Cause of the earth's magnetism.

or that the thermal and the magnetic equator are connected, as we had already proved to be the case with the thermal and magnetic poles. Captain Duperrey likewise attributes the differences in the magnetic intensities of different places to their difference of temperature; and he remarks, that in comparing the isothermal and the isodynamic lines, he has found a remarkable analogy in their curvatures, and particularly in the direction of their concavities and convexities. In support of these views, Captain Duperrey refers to the changes in the daily variation, as following the movements of the sun; and he infers that the southern hemisphere of our globe is a degree colder than the northern hemisphere.

But though it is now placed beyond a doubt, that the phenomena of temperature and magnetism are closely connected, and that the latter are powerfully influenced by the former, yet various questions arise, which it is very difficult to answer.

1. Have the phenomena of terrestrial magnetism an electric origin; that is, is the magnetism developed by electro-magnetic or thermo-magnetic causes? or,

2. Are the phenomena owing to the diffusion of iron or other magnetic metals through the solid mass of our globe, in which magnetism is induced by some exterior cause?

The electro-magnetic hypothesis, which was first stated by Sir David Brewster, has been ably supported by Professor Barlow, in a recent paper (*Phil. Trans.* 1831) *On the probable Electric Origin of all the Phenomena of Terrestrial Magnetism;* in which he considers it as probable, "that magnetism, as a distinct quality, has no existence in nature." As all the phenomena of terrestrial magnetism can be explained on the supposition that the magnetic power resides on its surface, it occurred to Mr Barlow, that if he could distribute over the surface of an artificial globe a series of galvanic currents, in such a way that their tangential power should everywhere give a corresponding direction to the needle, this globe would exhibit, while under electrical induction, all the magnetic phenomena of the earth upon a needle freely suspended above it. He accordingly put this idea to the test of experiment in the following manner:

Barlow's electro-magnetic globe.

"I procured," says he, "a wooden globe sixteen inches in diameter, which was made hollow for the purpose of reducing its weight; and, while still in the lathe, grooves were cut to represent an equator, and parallels of latitude at every 4½° each way from the equator to the poles; these grooves were about an eighth of an inch deep and broad; and lastly, a groove of the same breadth, but of double the depth, was cut like a meridian, from pole to pole, half round. These grooves were for the purpose of laying in the wire, which was effected thus: The middle of a copper wire, nearly ninety feet long, and one-tenth of an inch in diameter, was applied to the equatorial groove, so as to meet in the transverse meridian; it was then made to pass round this parallel, returned again along the meridian to the next parallel; then passed round this again; and so on, till the wire was thus led in continuation from pole to pole.

"The length of wire still remaining at each pole was bound with varnished silk to prevent contact, and then returned from each pole along the meridian groove to the equator. At this point, each wire being fastened down with small staples, the wires for the remaining five feet were bound together to near their common extremity, where they opened to form two points for connecting the poles of a powerful galvanic battery.

"When this connection was made, the wire became of course an electric conductor, and the whole surface of the globe was put into a state of transient magnetic induction; and consequently, agreeable to the laws of action above described, a neutralized needle freely suspended above such a globe would arrange itself in a plane passing from pole to pole through the centre, and take different angles of inclination, according to its situation between the equator and either pole.

"In order to render the experiment more strongly representative of the actual state of the earth, the globe, in the state above described, was covered by the gores of a common globe, which were laid on so as to bring the poles of this wire arrangement into the situation of the earth's magnetic poles, according to the best observations we have for this determination. I therefore placed them in latitude 72° north and 72° south, and on the meridian corresponding with longitude 76° west, by which means the magnetic and true equators cut one another in about 14° east, and 166° west longitude.

"The globe being thus completed, a delicate needle must be suspended above it, neutralized from the effect of the earth's magnetism, according to the principle I employed in my observations on the daily variation, and described in the Philosophical Transactions for 1823; by which means it will become entirely under the superficial galvanic arrangement just described. Conceive now the globe to be placed so as to bring London into the zenith, then the two ends of the conducting wire being connected with the poles of a powerful battery, it will be seen immediately that the needle, which was before indifferent to any direction, will have its north end depressed about 70°, as nearly as the eye can judge, which is the actual dip in London; it will also be directed towards the magnetic poles of the globe, thereby also showing a variation of about 24° to 25° to west, as is also the case in London. If now we turn the globe about on its support, so as to bring to the zenith places equally distant with England from the magnetic pole, we shall find the dip remains the same; but the variation will continually change, becoming first zero, and then gradually increasing to the eastward, as happens on the earth. If again we turn the globe so as to make the pole approach the zenith, the dip will increase, till at the pole itself the needle will become perfectly vertical. Making now this pole recede, the dip will decrease, till at the equator it vanishes, the needle becoming horizontal. Continuing the motion, and approaching the south pole, the south end of the needle will be found to dip, increasing continually from the equator to the pole, where it becomes again vertical, but reversed as regards its verticality at the north pole."

Although the artificial globe represents very exactly on a small scale all the phenomena of terrestrial megnetism, and although, as Mr Barlow says, "he has proved the existence of a force competent to produce all the phenomena, without the aid of any body usually called magnetic;" yet he acknowledges that, "we have no idea how such a system of currents can have existence on the earth, because, to produce them, we have been obliged to employ a particular arrangement of metals, acids, and conductors." The discovery of Dr Seebeck, however, that the mere application of heat to a circuit composed of two metals[1] is capable of developing the magnetic effects above described, is regarded by Professor Barlow as bringing us a step nearer to an explanation of the earth's magnetism, by referring us to nature as the great agent of all these phenomena, and he conceives that only one link is wanting to complete the explanation. This link, however,

---

[1] Mr Sturgeon of Woolwich has produced similar effects by the application of heat to only one metal, viz. a rectangle of bismuth only.

Terrestrial Magnetism.

is a very important one, and we are just as much puzzled to discover the metallic thermo-magnetic apparatus, as we are to discover the electro-magnetic one. If it could be shown that the action of solar heat is capable of developing magnetism in particles such as those which are known to constitute our globe, the great difficulty would be removed; but until this is done, we are disposed to lean to the old though not yet exploded notion, that terrestrial magnetism is the effect of magnetic or ferruginous materials, which are disseminated through the mass of the earth. This leads us to consider the second question relative to the origin of terrestrial magnetism.

2. Are the phenomena owing to the diffusion of iron or other magnetic metals through the solid mass of our globe, on which magnetism is induced by some exterior cause?

In so far as our knowledge extends, iron and other magnetic metals are not so regularly diffused as to produce the magnetic phenomena; and we are not entitled to assume the existence of any regular metallic nucleus, or regular arrangement of metallic strata, capable of producing that uniform action in the magnetic needle which is indicated by the regularity of the isodynamical lines, or those of equal magnetic intensity. That there are actual magnets within the crust of our globe, and abundance of ferruginous matter capable of producing locally magnetic phenomena, cannot be doubted; but the action of these two classes of bodies is regulated by different laws, and we can only regard them as exercising a disturbing force in rendering irregular the action of some more general cause. If the ferruginous matter which produces magnetism is situated near the surface of the earth, we should expect a diminution in the intensity when the needle is made to oscillate above the deepest parts of the ocean, where the solid crust may be many miles distant. If it is, on the other hand, deeply seated, the intensity ought to diminish greatly as we ascend in balloons, or to the tops of our highest mountains; but none of these effects are observed, and it becomes therefore very improbable that the magnetic phenomena are produced either by ferruginous matter *near the surface, or far removed from it.*

Terrestrial magnetism supposed to reside in the atmosphere.

But though we cannot find the seat, or rather the intermedium, of terrestrial magnetism in the bowels of the earth, may we not, as a last resource, seek for it *in our atmosphere?* It appears to be demonstrated by the experiments of Fusinieri, of which we have given a full account in our article on ELECTRICITY, that metals, and *particularly iron,* exist in a state of vapour in our atmosphere; and hence we have a regular hollow shell of magnetic matter enveloping the earth, and capable, when magnetism is induced upon it by an exterior cause, of producing all the phenomena of terrestrial magnetism. In its undisturbed state of equilibrium, this magnetic atmosphere will act upon the needle, according to the laws which Mr Barlow found to regulate the action of an iron sphere or shell; but these laws will be modified by those which regulate the thermal state of the globe, and will be disturbed by sudden changes of temperature, and by the various electrical agencies which exercise so powerful an influence over the meteorological condition of the atmosphere. The more violent disturbances of electrical equilibrium will fuse, and throw down in the form of meteoric stones, the metallic vapour in their vicinity. Inferior electrical actions will render their progress visible in the form of lightning and fiery meteors, arising from the heated state of the metallic particles; while still feebler electricities will, by their accompanying heat, produce the sheets of summer lightning, and the more continued and shifting phenomena of the aurora. Hence the electric sounds and other accompaniments of the aurora; hence its connection with the magnetic pole and equator; and hence the disturbance of the needle, or the *magnetic hurricanes,* as Humboldt calls them, while the regular action of the metallic atmosphere is disturbed during the prevalence of the aurora, or of thunder storms. These views receive some support from the observations of MM. Gay-Lussac and Biot, from which it appears that the intensity of terrestrial magnetism is not diminished at the height of 13,000 feet above the earth; and Mr Henwood found the magnetic intensity as strong 710 feet above the level of the sea, as at the bottom of a mine 950 feet below the same level. Kupffer, on the authority, we believe, of a single observation, has given an opposite opinion; and Saussure conceived that the intensity was less on the Col de Geant than at Geneva, but the numbers which he gives actually authorizes the opposite conclusion.

Terrestrial Magnetism.

From a series of observations made in July 1830, by M. Quetelet, in Switzerland, it appears, that in place of the intensity diminishing with the height, it actually increases, the increase taking place gradually (with the exception of Bonneville) in ascending from Geneva to the Col de Balme, as is shown in the following table:

	Horizontal Intensity.
Geneva	1·0805
Bonneville	1·0765
Sallenches	1·0815
St Gervais	1·0861
Vaudagnes	1·0884
Servoz	1·0872
Mer de Glace	1·0885
Chamouni	1·0935
Col de Balme	1·0917
Martigny	1·0921
Hospice St Bernard	1·0966
Simplon village	1·0987
Domodossolo	1·0997

But an argument of still more weight may be derived from the admitted fact, that a *powerful source of magnetism actually exists in our atmosphere,* and that the south pole of the needle has a distinct connection with the source of this magnetism. This source of magnetism is the *aurora borealis,* and the south pole of the dipping needle points to the focus to which the beams of the aurora converge. These beams act as magnets, as we have seen in a previous section; the action of our magnetic atmosphere, when undisturbed by any other cause but that of temperature, tends to fix the needle in a specific direction, which varies within certain limits, depending on the ordinary changes of temperature; but when the regular magnetism of the atmosphere is disturbed by electric or other causes, the needle must necessarily be affected by the displacement or altered temperature of the magnetic matter, as exhibited in the motions and variations in the lustre of the beams of the aurora. The magnetic pole, therefore, in our hemisphere, will be a north pole attracting the south end of the needle, and creating an elevation of the south end in place of a dip of the north end.

By the aid of these views, all the magnetic phenomena of the aurora borealis, so ably described by Dr Dalton, and the disturbances of the needle, so accurately observed by M. Arago, in reference to auroræ that occurred in every part of the northern hemisphere, may be satisfactorily explained, as we have attempted to do in a preceding section.

In seeking for a cause which is capable of inducing magnetism on the ferruginous matter of our globe, whether we place it within the earth or in its atmosphere, we are limited to the SUN, to which all the magnetic phenomena have a distinct reference; but whether it acts by its heat or by its light, or by specific rays, or influences of a magnetic nature, must be left to future inquiry. Without placing any reliance on the observations which have been supposed to indicate a magnetic action in the violet rays, we attach some importance to the observations of Barlocci and Zantedeschi, who found that both natural and artificial magnets had their magnetism greatly increased by exposure to the common solar rays; a result which could not arise from their heating power, as an increase of temperature invariably diminishes the power of magnets.

Dalton's views respecting the aurora.

In the work of Dr Dalton, published in 1793, to which we have already referred, there are several ingenious hypothetical views respecting the cause of the aurora borealis and its magnetic influence, with which we were not acquainted till the sections on that subject were written; but as these views strongly confirm the hypothesis of terrestrial magnetism which we have ventured to bring forward, we shall state as briefly as we can the leading ideas of Dr Dalton.

1. *The region of the aurora* is 150 miles above the earth's surface. Immediately above the earth's surface is the region of the clouds, then the region of meteors called falling stars and fire-balls, and beyond this region is that of the aurora. In proof of the great height of the aurora (independent of actual measurement) Dr Dalton adduces its extremely attenuated light, which, he says, may spread over one half of the hemisphere, and not yield more light than the full moon. "This," he continues, "arises from the extreme rarefaction of the air, which is almost tantamount to a Toricellian vacuum; in fact, the light of the aurora exactly corresponds with that of the electric spark when sent through a tube in which the air has been rarefied to as high a degree as can be effected by a good air-pump."

2. *The matter of the aurora.*—"From the conclusions in the preceding section," says Dr Dalton, "we are under the necessity of considering the *beams* of the *aurora borealis* of a *ferruginous* nature, because nothing else is known to be magnetic; and consequently that there exists in the higher region of the atmosphere an electric fluid, partaking of the properties of *iron*, or rather of *magnetic steel;* and that this fluid, doubtless from its magnetic property, assumes the form of cylindric beams." "My *fluid of magnetic matter*," adds Dr Dalton in another place, "is, like magnetic steel, a substance possessed of the properties of magnetism." "Whether any of the various kinds of air or elastic vapour we are acquainted with is magnetic, I know not, but hope philosophers will avail themselves of these hints to make a trial of them."

3. *Exciting cause of the magnetism of the aurora.*—"With regard to the exciting cause of the aurora, I believe it will be found in change of temperature." "Nothing is known to affect the magnetism of steel; heat weakens or destroys it; electricity does more, it sometimes changes the pole of one denomination to that of another, or inverts the magnetism. Hence we are obliged to have recourse to one of these two agents, in accounting for the mutations above mentioned. As for heat, we should find it difficult, I believe, to assign a reason for such sudden and irregular productions of it in the higher regions of the atmosphere, without introducing electricity as an agent in these productions; but rather than make such a supposition, it would be more philosophical to suppose electricity to produce the effect on the magnetic matter *immediately*." "The beams of the *aurora* being magnetic, will have their magnetism weakened, destroyed, or inverted, *pro tempore*, by the several electric shocks they receive during an aurora."

4. *The nature of the magnetism of the beams of the aurora.*—Dr Dalton conceives the magnetism to be permanent, and not induced; and *each beam to be as it were a separate magnet*, with the regular polarity of permanent magnets. "I conceive that a beam may have its magnetism inverted, and exist so for a time, &c....and I farther conceive, that when the beam is restored to its natural position of the north pole downward, it is effected, not by inverting the beam wholly as a beam (for this is never observed in an aurora), but by inverting the constituent particles, which may easily be admitted, of a fluid."

"If a magnet be required to be made of a given quantity of steel, it is found by experience to answer best when the length is to the breadth as 10 to 1 nearly. It is a remarkable circumstance, that the length and breadth of the magnetic beams of the aurora should be so nearly in that ratio. Query, If a fluid mass of magnetic matter, whether elastic or inelastic, were swimming in another fluid of equal density, and acted on by another magnet at a distance, what form would the magnetic matter assume? Is it not probable it would be that of a cylinder, of proportional dimensions to the beams of the *aurora?*"

5. *Governing cause of the magnetism of the aurora.*—"As the beams," says Dr Dalton, "are swimming in a fluid of equal density with themselves, they are in the same predicament as a magnetic bar or needle swimming in a fluid of the same specific gravity with itself; but this last will only rest in *equilibrio* when in the direction of the *dipping needle*, owing to what is called the *earth's magnetism;* and as the former also rests in that position only, the effects being similar, we must, by the rules of philosophising, ascribe them to the same cause. Hence then it follows, that THE AURORA BOREALIS IS A MAGNETIC PHENOMENON, AND ITS BEAMS ARE GOVERNED BY THE EARTH'S MAGNETISM." "I am aware that an objection may be stated to this; if the beams be swimming in a fluid of equal density, it will be said they ought to be drawn down by the action of the earth's magnetism. Upon this I may observe, that it is not my business to show why this is not the case, because I propose the magnetism of the beams as a thing demonstrable, and not as a hypothesis. We are not to deny the cause of gravity because we cannot show how the effect is produced. May not the difficulty be lessened by supposing the beams of less density than the surrounding fluid?"

Although this brief abstract of Dr Dalton's essay contains many views which in their general bearing add to the probability of the hypothesis which we have maintained, yet we must state in a few words the difference between the two hypotheses.

1. According to our views, terrestrial magnetism resides wholly in the earth's atmosphere, which contains throughout its whole extent ferruginous and other metallic matter, and sulphureous exhalations, all of which are carried off by evaporation, by ejection from volcanoes, and by the returning strokes of electricity from the earth to the air. The actual existence of such materials in the atmosphere, particularly sulphureous and ferruginous matter, is proved by the observations of Fusinieri, and by the existence of meteoric stones and other solid substances which fall on the earth.

2. The magnetism which directs the needle is induced upon the magnetic matter in the atmosphere, like that of an iron sphere, by some exterior cause, although it is very probable that small local effects may be produced by ferruginous matter within the earth, and near its surface; but the only effect of these will be to produce small irregularities in the intensity of the magnetism of the needle, and in its direction.

3. As the colour of the electric spark, when taken from different bodies, or when passing through different media, depends on the solid matter which it renders luminous, so the different colours of lightning, of the auroral beams, of falling stars, and of meteors of every kind, are produced by the heat of the electric fluid either rendering the material substance visible by incandescence, or throwing it into a state of combustion.

4. The beams of the aurora are those portions of the

Methods of making Artificial Magnets.

magnetic atmosphere through which electricity is passing, and which, by being heated to different degrees, are brought to different states of incandescence, and have their induced magnetism increased, like that of all ferruginous bodies which are brought to a temperature less than that of white heat.

Although it is universally admitted that a source of magnetism has been proved to exist in our atmosphere, and though it is evident that the force which emanates from it is greater than any magnetic force which can be proved to have its origin in the solid part of the earth, yet it may be asked if there is any reason for believing that the magnetism in the atmosphere is strong enough to be considered as the only source of terrestrial magnetism. To this question, some of the facts already stated afford a pretty satisfactory answer. M. Arago has shown that the auroræ which exist only at St Petersburg, in Siberia, and even in North America, actually disturb the magnetic needle at Paris; and he considers it highly probable that the auroras even round the south pole of our globe extend their influence to Paris. If a force of such magnitude exists in insulated beams which form regular magnets, according to Dr Dalton, we need not scruple to suppose that a ferruginous atmosphere is capable of producing that degree of intensity which characterises terrestrial magnetism, and that the disturbances exhibited at Paris on the magnetic needle are the effect of local diminutions or augmentations of the magnetic force in Siberia, America, or even in the southern hemisphere.

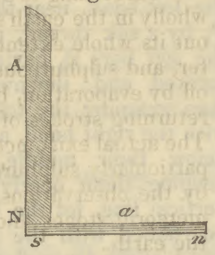
CHAP. X.—ACCOUNT OF THE DIFFERENT METHODS OF MAKING ARTIFICIAL MAGNETS.

Methods of making artificial magnets.

In the history of magnetism we have already made a brief reference to the principal methods of making artificial magnets. We shall now proceed to give a short account of the methods themselves.

In the infancy of the science, a bar B of hard steel was magnetised by rubbing it throughout its whole length on one of the poles N of a natural or artificial magnet A, in a direction at right angles to the line joining the two poles of the primitive magnet. By this process the new bar *a* will be rendered slightly magnetic, but its magnetism cannot possibly be completely developed unless in the two cases where the new bar is extremely small, or the primitive magnet A extremely powerful; and the magnetism which is communicated often exhibits different poles, or consequent points as they are called, throughout the length of the new bar.

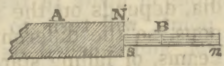
Fig. 53.



In using this method, the exciting pole should be slightly pressed upon the new bar; and after reaching the end of the bar at *s*, it must be lifted up and applied again to the other end, the friction being always made in the same direction.

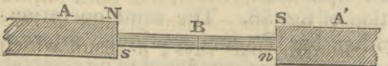
Another old method of making magnets consisted in placing the end *s* of a new bar B *in contact* merely with one of the poles N of a powerful magnet, and striking the new bar so as to make it ring during the time of its application. This method, however, like the first, will be effectual only for very small bars; the pole *s* will be the strongest, and the neutral point at B will be nearer *s* than *n*.

Fig. 54.



A more efficacious method of magnetising small bars by simple contact is shown in the annexed figure, by placing the new bar B between the opposite poles N, S of two strong magnetic bars A, A′, of nearly equal power. In this case the magnetism of B will be nearly twice as great as when only one, B or A, is used; and if there are no consecutive poles produced, the neutral point B will bisect *ns*.

Fig. 55.



Methods of making Artificial Magnets.

These simple methods were discontinued when the principles of magnetic induction were better understood, and several ingenious and highly effective processes of making artificial magnets were invented by the philosophers of the eighteenth century. The first of these was that of Mr Knight.

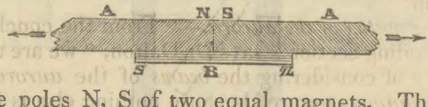
Sect. I.—*Account of Dr Gowin Knight's method of making Artificial Magnets.*

Knight's method.

Dr Gowin Knight, a physician in London, was long celebrated for the excellence of the artificial magnets which he made. The method which he used was kept a secret during his life, but was published after his death by Mr Wilson.

The bar or needle B, which he intended to magnetise, was tempered at a *cherry red heat*, and placed under the opposite poles N, S of two equal magnets. These magnets are then separated in opposite directions SA′, NA, so that the south pole S of the one passes over the *north polar* half B*n* of the bar B, and the north pole N of the other, over the *south polar* half B*s* of B. This operation is repeated several times, till the magnetism of the bar B is fully developed.

Fig. 56.



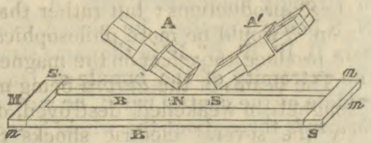
In this process the north pole N, while it attracts to the half B*n* all the south polar magnetism in B*s*, repels at the same time into B*s* all the north polar magnetism of B*n*. The same is true, *mutatis mutandis*, with the south pole S. When the bars A, A′ are large and powerful, it has been found that this process is capable of communicating to small bars all the magnetism of which they are susceptible.

Sect. II.—*Account of Duhamel's method of making Artificial Magnets.*

Duhamel's method.

After Dr Knight's process had been known and used, the artificial magnets which were made by it were in great request, and distributed throughout Europe. When the process, however, was applied to bars of great size, it was found to be defective; and M. Duhamel of the Academy of Sciences, in conjunction with M. Antheaume, set themselves to devise a better method, which is represented in the annexed figure. The bars B, B′ to be magnetised are placed parallel to each other, and have their extremities united by two pieces M, *m* of soft iron, at right angles to the bars. He then took two strong magnets A, A′, or two bundles of small bar-magnets, the bars of each bundle having their similar poles together; and having placed them, as in the figure, at an angle of about

Fig. 57.



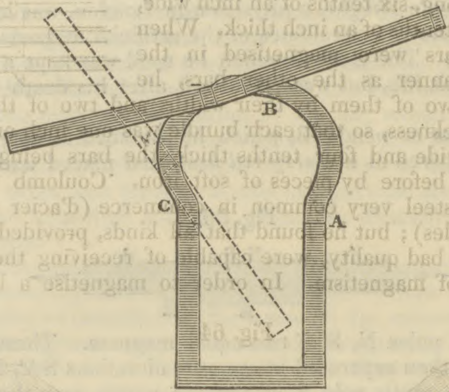
Methods of making Artificial Magnets.

90°, or inclined 45° to the bar B, they were separated from each other as already described in the explanation of fig. 56. The same operation was repeated on the other bar B′, and continued alternately on both till the magnetism was supposed to be completely developed in both bars. When A and A′ are placed upon the second bar B′, the disposition of the poles must be reversed, the pole that was formerly to the right hand being now placed to the left. The two bars B, B′ are then turned, so that the undermost faces are uppermost, and the same process carried on as before.

The distinctive peculiarity of Duhamel's process consists in the employment of the pieces of iron M, *m*, and in the use of bundles of small bars, which are more efficacious than two single ones of the same size.

The very same method is applicable to curved bars, or those of the horse-shoe form, as shown in the annexed figure, where the inclined bars are carried round the curved bar A, B, C, exactly as they were along the straight bar B.

Fig. 58.

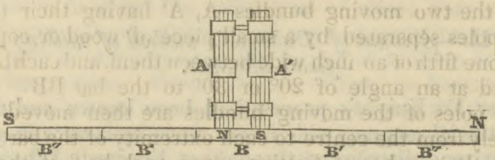


Sect. III.—*Account of Mr Michell's method of making Artificial Magnets.*

Michell's method of double touch.

About the same time that Duhamel was occupied with this subject, Mr Michell of Cambridge and Mr Canton were separately engaged in the same inquiry. Mr Michell published his method in 1750, to which he gave the name of the *method of double touch.* Having joined together, at the distance of a quarter of an inch, two bundles of strongly magnetised bars A, A′, their opposite poles N, S being together, he placed five or more equal steel bars B, B′, B′, B″, B″ in the same straight line; and resting the extremity of the bundle of magnets A, A′ upon the middle of the central bar B, he moved them *backwards* and *forwards* throughout the whole length of the line of bars, repeating the operation on each side of the bars, till the greatest possible effect was produced. By this method Mr Michell found that the middle steel bars B, B′, B′ acquired a very high degree of magnetic virtue, and greater than the outer bars B″, B″; but by placing these last bars in the middle of the series, and repeating the operation, they acquired the same degree of magnetism as the rest.

Fig. 59.



Mr Michell states, that two magnets will, by his process of double touch, communicate as strong a magnetic virtue to a steel bar, as a single magnet of five times the strength, when used in the process of single touch. The bars A, A′ act with the sum of their powers in developing magnetism in all parts of the line of bars between them, and with the difference of their powers in all parts of the line of bars beyond them. The external bars act the same part in this process as the two pieces of soft iron in the method of Duhamel.

Methods of making Artificial Magnets.

Sect. IV.—*Account of Canton's method of making Artificial Magnets.*

Canton's method.

In the year 1751 Mr Canton published his process, which he regarded as superior to preceding ones. He placed the bars as in Duhamel's method, joined by pieces of soft iron. He then applied Michell's method of double touch, and afterwards he separated the two bundles of magnets A, A′, and having inclined them to each other, as in Duhamel's method, he made them rub upon the bar from the middle to its extremities. The peculiarity of Canton's method is the union of these two processes; but Coulomb and others are of opinion that the latter part of the process is the only effectual one.

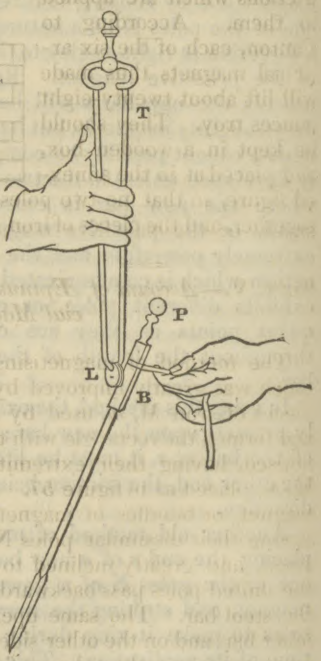
Without natural or artificial magnets.

In order to make artificial magnets without the aid either of natural loadstones or artificial magnets, Mr Canton gives the following detailed process.

He takes six bars of soft and six of hard steel, the former being smaller than the latter. The bars of *soft* steel should be three inches long, one fourth of an inch broad, and one twentieth thick; and two pieces of iron must be provided, each having half the length of one of the bars, and the same breadth and thickness. The bars of *hard* steel should be each five and a half inches long, half an inch broad, and three twentieths of an inch thick, with two pieces of iron of half the length, and the same breadth and thickness.

All the bars being marked with a line quite round them at one end, take an iron poker and tongs, or two bars of iron, the larger and the older the better, and fixing the poker P upright, as in fig. 60, hold to it with the left hand, near the top P, by a silk thread, one of the *soft* bars B, having its marked end downwards; then grasping the tongs T with the right hand, a little below their middle, and keeping them nearly in a vertical line, let the bar B be rubbed with the lower end L of the tongs, from the marked end of the bar to its upper end, about ten times on each side of it. By this means the bar B will receive as much magnetism as will enable it to lift a small key at the marked end; and this end of the bar being suspended by its middle, or made to rest on a point, will turn to the *north,* and is called its *north* pole, the unmarked end being the *south* pole.

Fig. 60.

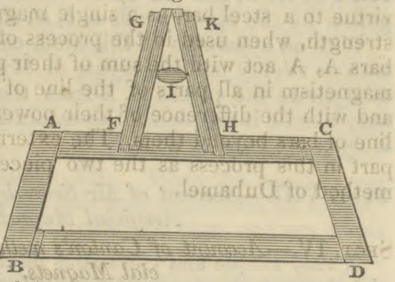


When four of the soft steel bars are thus rendered magnetic, the other two AC, BD must be laid parallel to each other, at the distance of about one fourth of an inch, as in

Methods of making Artificial Magnets.

the figure, having their dissimilar poles united with the smallest pieces of iron AB, CD. Two of the magnetised bars are then to be placed together as at G, with their similar poles united, and the other two as at K; and when separated by a piece of wood I, they are slid four or five times backwards and forwards along the whole length of the bar AC, so that the marked end F of G is nearest the unmarked end of AC, and *vice versa*. This operation is carefully repeated on BD, and on the other sides of both AC and BD. When this is done, the bars AC, BD are to be taken up and substituted for the two outer bars of the bundles G, K, these last being laid down in the place of the former, and magnetised in a similar manner. This operation must be repeated till each pair of the soft bars has been magnetised *three* or *four* times.

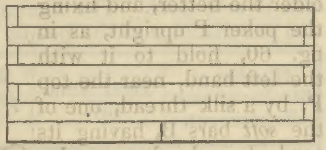
Fig. 61.



When the six soft bars are thus magnetised, they must be formed into two bundles of three each, with their similar poles together, and must be used to magnetise two of the *hard* bars in the manner already described; and when they are magnetised, other two of the hard bars must be touched in a similar manner. The soft bars are now to be laid aside, and the remaining two hard bars magnetised by the *four* hard bars already rendered magnetic; and when this is done the operation should be repeated by interchanging the hard bars, till they are impregnated with the greatest degree of permanent magnetism which this method is capable of communicating to them.

In performing the above operations, which may be completed in about half an hour, the bars AC, BD, and the pieces AB, CD should be placed in grooves, or fixed between pins of wood or brass, to keep them steady during the successive frictions which are applied to them. According to Canton, each of the six artificial magnets thus made will lift about twenty-eight ounces troy. They should be kept in a wooden box, and placed as in the annexed figure, so that no two poles of the same name may be together, and the pieces of iron AB, CD placed beside them.

Fig. 62.



SECT. V.—*Account of Æpinus's method of making Artificial Magnets.*

Æpinus's method.

The method of magnetising steel bars by the double touch was greatly improved by Æpinus. In place of the pieces of iron M, *m*, used by Duhamel, he used magnets, and formed the rectangle with the two steel bars to be magnetised, having their extremities united by two magnets M, *m*, placed as in figure 57. He then placed the original magnet, or bundles of magnets, A, A′, as in the figure, having their dissimilar poles N, S separated by a piece of wood, and greatly inclined to each other; and he made the united poles pass backwards along the whole length of the steel bar. The same operation was repeated on the other bar, and on the other side of each of them, care being taken to reverse the poles, as formerly mentioned, when the rubbing bars are removed from the one steel bar to the other. Æpinus found that a maximum effect was produced when the bars A, A′ were inclined 20° or 30° to the steel bar over which they passed.

SECT. VI.—*Account of Coulomb's method of making Artificial Magnets.*

Methods of making Artificial Magnets.

Coulomb's method.

The method of making artificial magnets employed by Coulomb consists of the most efficacious parts of the preceding processes, improved and extended by long experience in the art. The apparatus which he uses consists of *fixed* and *moving* bundles of magnets. Each of the fixed bundles consists of *ten* bars of steel tempered at a cherry-red heat, their length being about twenty-one inches, their breadth six tenths of an inch, and their thickness one fifth of an inch. Having rendered them as strongly magnetic as possible, with a natural or an artificial magnet, he joined them with their similar poles together, and formed them into two beds of four bars each, these beds being separated by small rectangular parallelopipeds *m*, *n* of soft iron, projecting a little beyond their extremities, as shown in the annexed figure. The *moving* bundles consist of four bars tempered at a cherry-red heat, each being about sixteen inches long, six tenths of an inch wide, and two tenths of an inch thick. When these bars were magnetised in the same manner as the other bars, he united two of them by their widths and two of them by their thickness, so that each bundle was one inch and two tenths wide and four tenths thick, the bars being separated as before by pieces of soft iron. Coulomb used a kind of steel very common in commerce (d'acier timbré à 7 etoiles); but he found that all kinds, provided it was not of a bad quality, were capable of receiving the same degree of magnetism. In order to magnetise a bar, he placed the large fixed bundles M, N in the same straight line, and at a distance a little less than the length of the bar to be magnetised; and this bar BB′ was placed as in the figure, so as to rest on the projecting pieces of iron, so that the contact took place only over a length of one fifth of an inch; the two moving bundles A, A′ having their dissimilar poles separated by a small piece of wood or copper, about one fifth of an inch wide between them, and each being inclined at an angle of 20° or 30° to the bar BB′. The united poles of the moving bundles are then moved successively from the centre to each extremity of the bar BB′, so that the number of frictions upon each half of the bar may be equal. When the last friction has been given, the united poles are brought to the middle point of the bar BB′, and then withdrawn perpendicularly. The same operation is then repeated on the other side of the bar BB′. If we wish to employ the method of Duhamel in place of that of Æpinus, we do not require the piece of wood or copper, but have only to separate the bars when their united poles are in the middle of the bar BB′, making each pole pass to the extremity of it.

Fig. 63.

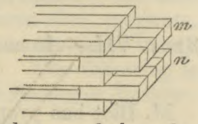


Fig. 64.

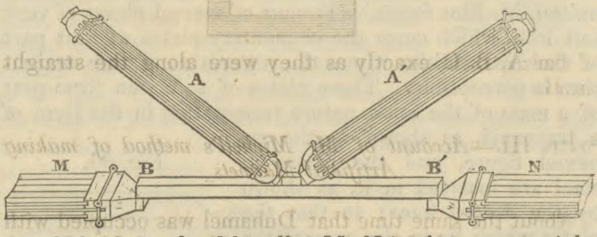
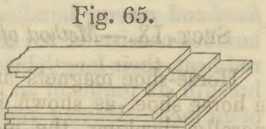


When the fixed and moving bundles are composed of bars which have not been magnetised to saturation, we must form new bundles with the newly magnetised bars, whose magnetism will be stronger than those by which they were magnetised, and by their heat magnetise anew the bars first used; and by repeating this process three or four times, the bars may be raised to the highest degree of magnetic virtue.

When the bars BB′ to be magnetised are very large, the moveable bundle should contain more than four bars, each of the bars retreating about half an inch in the direction of their thickness, as shown in the annexed figure. The advantage of this displacement arises from the fact, that the highest degree of magnetism resides in the extremity of the bar. Hence, by this arrangement, not only the most efficacious parts of the moving bar are brought into contact with the bar to be magnetised, and act more powerfully, but the bar nearest to the central one in the bundle tends not merely to maintain, but to augment, in its extremity, its degree of magnetism. The third bar produces the same good effect upon the second, and so on with the rest.

Fig. 65.

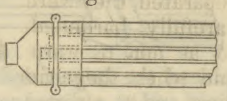


SECT. VII.—*Account of M. Biot's method of making Artificial Magnets.*

Biot's method.

M. Biot has proposed several important improvements on the process of Coulomb. As the bars are always bent a little in tempering, he recommends that they should at first be brought to as hard a temper as possible, and then annealed to the first shade of yellow. By this means they will have a sufficient degree of malleability to be again brought into shape, while they possess sufficient coercive power for receiving and retaining a high degree of magnetism. Regarding it as of essential importance to insure an intimate contact between the plates of the large bundles and the soft iron or armour by which they are united, M. Biot forms his armour of several plates of very soft iron, which cover the elementary plates at that part of their extremities where the repartition of free magnetism is perceptible. These plates of soft iron form part of a mass of the same nature terminating in the form of a trapezoid, as shown in the annexed figure, and the plates of steel are inserted in it, as shown by the dotted lines; so that the plates which lie in the axis of the bundles project a little beyond the lateral plates. The whole is then bound together with a collet of soft iron, held firmly by a screw. M. Biot remarks, that he has found from experience that this arrangement, indicated by theoretical considerations, is extremely advantageous.

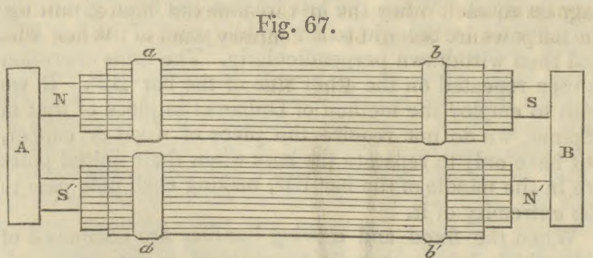
Fig. 66.



Coulomb's method of arming magnets.

Coulomb's method of fitting up, arming, and preserving his magnets, is shown in the annexed figure, representing two artificial magnets, armed at their extremities with two iron parallelopipeds, N, S, N′, S′; N, N′ being the north poles, and S, S′ the south poles. These parallelopipeds have their inner ends enveloped within the magnetic bars. The opposite poles N, S′, N′ S, are joined by pieces of soft iron A, B, and the bars of each magnet are held together by the upper bands a, b, a', b'.

Fig. 67.



With an apparatus of this kind, each part weighing fifteen or twenty pounds, eighty or 100 pounds is required to separate the pieces A, B from the poles, and an ordinary needle is magnetised to saturation by merely placing it upon the ends N S′ or N′ S.

SECT. VIII.—*Account of Mr Scoresby's method of making Artificial Magnets.*

Scoresby's method.

A very simple and efficacious method of making artificial magnets by percussion has been published by Mr Scoresby.[1] That iron became magnetic when struck by successive blows of a hammer in the direction of the dipping needle, was known to Dr Gilbert; but it is to Mr Scoresby that we owe a complete investigation of the subject. In order to determine the effects produced by percussion, Mr Scoresby used two methods, the one by observing the weight which the new magnet lifted, and the other by measuring the deviation which it produced on a magnetic needle. The following experiments were made with a cylindrical bar of soft steel six and a half inches long, one fourth of an inch in diameter, and weighing 592 grains. It was placed in a vertical position, resting on a piece of tin, and struck with a hammer of twelve ounces.

Number of Strokes at each Experiment.	Total Number.	Weight suspended by the Bar.	Deviation of the Needle; distance of Needle three Inches.
1	1	2	8°
1	2	0	10
5	7	4	12
10	17	6½	12½
5	22	6½	12½

When the steel bar was placed upon a stone, the effect was the same; but, as the following experiments show, a great increase of power was obtained by supporting the lower end of the bar upon the upper end of a large bar of iron or soft steel. The hammer weighed twelve ounces, and the distance of the needle was three inches.

Number of Strokes at each Experiment.	Total Number.	Weight suspended by the Bar.	Deviation of the Needle.
1	1	6½ grs.	13°
1	2	14	16
1	3	...	18
4	7	37	21
5	12	45	25
10	22	88	27
20	42	88	30
30	72	...	31
10	82	...	31½
By using a hammer weighing 22 ounces, an increased effect was produced.			
3	85	...	33
5	90	130	34

[1] *Philosophical Transactions*, 1822, part ii. p. 241

Methods of making Artificial Magnets.

From these experiments it follows, that a cylindrical bar of soft steel weighing 592 grains, can be made to lift only six and a half grains, when struck in a vertical position, with its lower end resting upon tin or stone; whereas the same bar, when struck with twenty-two blows upon a rod of iron suspended at its lower end, which was a north pole, lifted eighty-eight grains; by using a larger hammer, its lifting power increased to 130. When the steel bar was reversed, so that its south pole was uppermost, its magnetism was almost destroyed by a single blow, and two blows were sufficient to change its poles. Mr Scoresby found, that when the steel magnet was struck in the plane of the magnetic equator, its polarity also disappeared; but several blows were necessary to effect this change.

In another set of experiments on the effect of percussion on magnets, he employed a flat bar-magnet seven and seven tenths inches long, half an inch wide, one-seventh thick, and weighing 1170 grains.

When suspended vertically, with its south end uppermost, it produced, at the distance of eight inches, a deviation of 45° on the needle; but after 60, 80, and 100 blows, the deviation was reduced to 25°.

When the north pole was placed uppermost, other thirty blows reduced the deviation still farther, from 25° to 14°.

When the bar was again magnetised, and hammered upon a piece of tin, it produced a deviation of 50°; but after twenty blows, with the south pole uppermost, the deviation became 33°. By other sixty blows, with the north pole uppermost, the deviation became 24°.

From the results obtained in the preceding experiments, Mr Scoresby deduced the following method of making artificial magnets by percussion.

"I procured two bars of soft steel thirty inches long and an inch broad, also six other flat bars of soft steel eight inches long and half an inch broad, and a large bar of soft iron. The large steel and iron bars were not, however, absolutely necessary, as common pokers answer the purpose very well; but I was desirous to accelerate the process by the use of substances capable of aiding the development of the magnetical properties in steel. The large iron bar was first hammered in a vertical position; it was then laid on the ground with its acquired south pole towards the south, and upon this end of it the large steel bars were rested while they were hammered; they were also hammered upon each other. On the summit of one of the large steel bars, each of the small bars, held also vertically, was hammered in succession; and in a few minutes they had all acquired considerable lifting powers. Two of the smaller bars, connected by two short pieces of soft iron in the form of a parallelogram, were now rubbed with the other four bars, in the manner of Canton. These were then changed for two others, and these again for the last two. After treating each pair of bars in this way for a number of times, and changing them whenever the manipulations had been continued for about a minute, the whole of the bars were at length found to be magnetised to saturation, each pair readily lifting above eight ounces.

"In accomplishing this object, I took particular care that no magnetic substance was used in the process. All the bars were freed of magnetism before the experiment, so that none of them, not even the largest, produced a deviation of five degrees on the compass at three inches distance. Any bars which had been strongly magnetised, and had had their magnetism destroyed or neutralized (either by hammering, heating, or by the simultaneous contact of the two poles of another magnet placed transversely), I always found had a much greater facility for receiving polarity in the same direction as before, than the contrary. Hence it generally happened that one blow with the original north end downwards, produced as much effect as two or three blows did with the original south end downwards."

Methods of making Artificial Magnets.

By this ingenious process, any person who has no magnets within his reach, may communicate the strongest degree of permanent magnetism to hard steel bars of any magnitude, the bars magnetised by percussion being employed, as in the process of Coulomb, to magnetise the large bars which are required.

SECT. IX.—*Method of making Horse-Shoe Magnets.*

Method of making horse-shoe magnets.

Horse-shoe magnets are those which have the form of a horse shoe, as shown in fig. 58; and this form is, generally speaking, the most convenient for use, and for the preservation of their magnetic power. In all experiments where a large weight is to be lifted, the horse-shoe magnet is indispensable; and in consequence of the two poles being brought together, they may be substituted with great advantage for magnetising steel bars by the method of double touch.

In order to form a powerful magnetic battery, the best way is to unite a number of similar horse-shoe magnets, with their similar poles together, and to fix them firmly together in a case of copper or leather. The following is the method recommended and used by Professor Barlow: He took bars of steel twelve inches long, and having bent them into the horse-shoe shape, their length was six inches, their breadth one inch at the curved part, and three fourths of an inch at their extremities, and their thickness one fourth of an inch. They were filed very nicely, so as to correspond, and lie flatly upon each other. They were then drilled with three holes in each, as seen in the figure, and by means of screws V, V passing through these holes, *nine* horse-shoe bars were bound together. When the heads and ends of the screws were constructed, so as to leave the outer surfaces smooth, the mass of bars was filed as if they were one piece, and the surface made flat and smooth. When the bars were separated, they were carefully hardened, so as not to warp, and when they had been well cleaned and rendered bright, but not polished, they were magnetised separately in the following manner: When the two extremities of the bar are connected by a piece of soft iron M, the magnetism may be developed in the two halves by Duhamel's method, as in the annexed figure; or, following Æpinus, we may apply a strong magnet to each pole, and connect their extremities either with a piece of soft iron or another magnet, or we may apply two horse-shoe magnets to each other, as in the annexed figure, uniting the poles which are to be of contrary names. When the magnet or magnets are prepared in any of these ways, they are then to be magnetised with another horse-shoe magnet

Fig. 68.

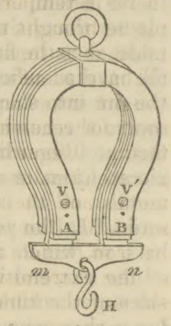

Fig. 69.

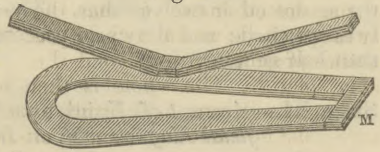

Fig. 70.

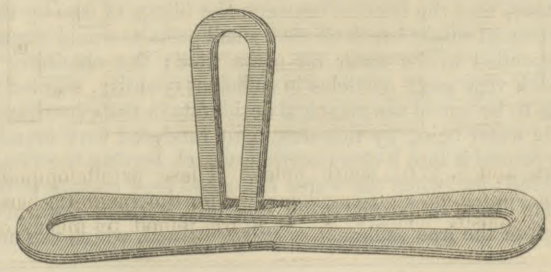

AB, by placing its north pole next to what is to be the south pole of one of the horse-shoe bars, and then carrying the moveable magnet round and round, but always in the same direction. In this way a very high degree of magnetic virtue may be communicated to each of the *nine* bars. When this is done, they are to be reunited by the three screws, and their poles or extremities connected by a piece of soft iron, or *lifter*, as in fig. 68, having at its middle a hook H for suspending any weight. As the lifting power depends on the accurate contact of the poles of the magnets with the lifter, the extremities should, after hardening, be properly rubbed down with putty upon a flat surface.

A magnet of this size and form was found by Professor Barlow to suspend *forty pounds;* but he afterwards found that a greater proportional power could be obtained by using bars that were long in comparison with their breadth.

Sect. X.—*Account of Professor Barlow's method of magnetising a number of Rectilineal Bars with a Horse-Shoe Magnet.*

Barlow's method of magnetising bars.

The following method of making artificial magnets is both a simple and efficacious one, and has been practised successfully by Professor Barlow. Having occasion for thirty-six magnets, twelve inches long, one and a fourth broad, and seven sixteenths of an inch thick, he placed thirty-six bars of steel, of these dimensions, on a table, so as to form a square, having nine bars on each side, the marked or north pole of each bar being in contact with the unmarked or south pole. At the angular points of the square the inner edges of the bars were brought into contact, and the external opening thus left was filled up by a piece of iron one inch and a quarter square and seven sixteenths of an inch thick. The horse-shoe magnet described in the preceding section was set upon one of the bars, so that its north pole was towards the unmarked end of the bar, and was then carried or rubbed along the four sides of the bars; and the operation was continued till the horse-shoe magnet had gone twelve times round the square. Without removing the magnet, each bar was turned one by one, so as to turn their lower sides uppermost, and the horse-shoe magnet was made to rub along the four sides of the square other twelve times. The bars were then highly magnetised; and the whole process did not occupy more than half an hour.

Sect. XI.—*Account of Knight's method of forming Artificial Magnets with an Iron Paste.*

Knight's artificial magnets of paste.

Although the following method of making a magnetic paste has been given in almost every treatise on magnetism, and was kept a secret by its inventor, yet we have no distinct information that it has been found superior in any respect to steel as a vehicle of magnetism. Mr Benjamin Wilson communicated the method to the Royal Society after the death of Mr Knight.

"Having provided himself with a large quantity of clean filings of iron, Dr Knight put them into a tub that was more than one third full of clean water; he then, with great labour, worked the filings to and fro for many hours together, that the friction between the filings of iron by this treatment might break off such small parts as would remain suspended in the water for some time; the obtaining of which very small particles in sufficient quantity, seemed to him to be one of the principal desiderata in the experiment. The water being by this treatment rendered very muddy, he poured it into a clean earthen vessel, leaving the filings behind; and when the water had stood long enough to become clean, he poured it out carefully, without disturbing such of the iron sediment as still remained, which was now reduced to an almost impalpable powder. This powder was afterwards removed into another vessel, in order to dry it; but as he had not obtained a proper quantity of it by this first step, he was obliged to repeat the process many times. Having at last procured enough of this very fine powder, the next thing to be done was to make a paste of it, and that with some vehicle which could contain a considerable quantity of the phlogistic principle. For this purpose he had recourse to linseed oil in preference to all other fluids. With these two ingredients only he made a stiff paste, taking particular care to knead it well before he moulded it into convenient shapes. Sometimes, while the paste continued in its soft state, he would put the impression of a seal on several pieces, one of which is in the British Museum. This paste was then put upon wood, and sometimes on tiles, in order to bake or dry it before a moderate fire, at about a foot distance. The doctor found that a moderate fire was most proper, because a greater degree of heat made the composition frequently crack in many places.

"The time necessary for baking this paste was generally five or six hours before it attained a sufficient degree of hardness. When that was done, and the several baked pieces were become cold, he gave them their magnetic virtue in any direction he pleased, by placing them between the extreme ends of his magazine of artificial magnets, for a few seconds or more, as he saw occasion. By this method the virtue they acquired was such, that when any one of these pieces was held between any of his best ten-guinea bars, with its poles purposely inverted, it immediately of itself turned about to recover its natural direction, which the force of these very powerful bars was not sufficient to counteract."[1] After giving the preceding method, M. Biot remarks that it consists in procuring a very fine powder of iron a little oxidated, all the particles of which he united by means of linseed oil, or any other substance fitted to give them a proper degree of oxygenation. "When this paste was magnetised," he continues, "each particle of the powder became a small magnet, in which the development of the magnetism might be very powerful, on account of the suitable degree of coercive power produced by the oxygenation; and the homogeneity of this state in all the particles, as well as their extreme tenuity, might give to the whole system the most favourable arrangements for receiving a high degree of magnetism." M. Biot conceives that a somewhat analogous effect might be obtained by steel of an equal and homogeneous grain, the carbon giving a coercive power like oxygen; but he thinks that the paste is likely to form better magnets. He is of opinion also that some powerful natural magnets may owe their virtue to the union of similar qualities.

Dr Fothergill, who had seen Mr Knight's paste magnets in his own possession, says that the mass had the appearance of a piece of black lead, though less shining. He informs us also of a very remarkable fact, if it be true, that while the poles of a natural loadstone, or of the hardest steel magnet, could be changed, those of the paste magnets were immoveable. A small piece, of about half an inch square and one fourth thick, was powerfully magnetic though unarmed; and its poles could not be altered though it was placed between two of Mr Knight's largest and most strongly impregnated magnetic bars.[2]

Conceiving that the powder which formed the basis of this paste was the *black oxide of iron*, or *martial Ethiops,* M. Cavallo has given the following receipt for imitating natural magnets; but he does not say that the magnets made by it are better than those of steel. "Take some martial Ethiops reduced into a very fine powder, or, which is more easily procured, *black oxide of iron*, the scales which fall from red-hot iron when hammered, and are

Methods making rtificial Magnets.

found abundantly in smiths' shops. Mix this powder with drying linseed oil, so as to form it into a very stiff paste, and shape it in a mould so as to give it any form you require, whether of a terella, a human head, or any other. This done, put it into a warm place for some weeks, and it will dry so as to become very hard; then render it magnetic by the application of powerful magnets, and it will acquire a *considerable* power."

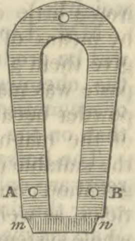
SECT. XII.—*Account of the method of arming and preserving Natural and Artificial Magnets.*

n arming d pr rving agnets.

We have already stated, that when a piece of soft iron is suspended at the pole of a magnet, this piece of iron is rendered magnetic, and that a second and a third smaller piece of iron suspended from the other piece of iron also become magnetic, the magnet developing magnetism in the first piece of iron, the first piece developing it in the second, and so on. Each piece of iron re-acts as a magnet on the larger piece on which it hangs, improving or increasing the development of its magnetism. Hence the lifting power of a magnet may be increased by suspending to one of its poles, day after day, a small additional piece of iron.

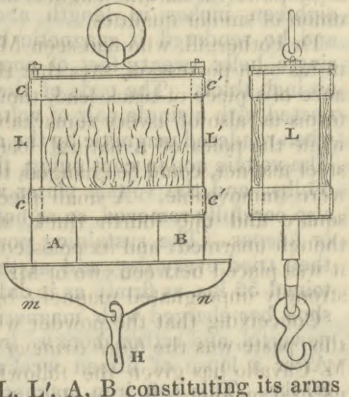
On this property is founded the method of arming natural and artificial magnets, for the purpose both of increasing and preserving their magnetic power. In order to support the greatest weight with any magnet, both its poles should be brought in action. In the horse-shoe magnet this is easily done, so that the *armature* for it is made by merely placing a piece of soft iron *mn* upon its poles A (north) B (south), having a hook attached to it for hanging on weights, as in fig. 68. That the power of this magnet is not only increased but preserved, is easily proved; but the following striking experiment of Mr Watkins affords the most beautiful illustration of the principle. He magnetised a horse-shoe bar *of soft iron*, made of a bar nineteen inches long and one inch square, when its poles A, B were joined by another piece of iron *mn*, and he found that it preserved its magnetic virtue for a long time,[1] while its poles were thus united. The moment, however, that the armature *mn* was removed, the magnetism of the horse-shoe bar almost wholly disappeared.[2]

Fig. 71.



The best armature for a natural magnet is shown in the annexed figure, where L, L′ are two broad pieces of soft iron applied to the poles, and projecting on one side of it. To these projecting ends or transferred poles A, B a piece of iron *mn* is applied, so as to touch them both, as in the horse-shoe magnet in fig. 68. The lateral pieces of iron L, L′ are commonly held firm to the magnet by means of a box of brass, silver, or copper *cc′c′*, and the magnet is then said to be armed, the pieces of iron L, L′, A, B constituting its arms or armature.

Fig. 72.



A loadstone armed in the preceding manner may be strengthened by Professor Barlow's method of magnetising horse-shoe magnets; and if we suspend a scale or bag from the hook H, and add, day after day, some additional weight, it may be made to suspend *two* or *three* times the weight that it could lift if applied to it at once. If its force, however, is overpowered by too great a load, its strength will revert to what it was at first; but if we take out of the scale a certain part of the load which it can suspend, we may again proceed to add more weight gradually, till it carries its maximum load.

Methods of making Artificial Magnets.

In order to preserve loadstones and magnets, their armature should always be applied to them. They should be kept in a cool place, free from vibrations, and rough treatment of every kind. Bar-magnets should always be kept with their dissimilar poles together; and both single magnets and needles will have their power not only preserved, but increased, by keeping them surrounded with a mass of dry filings of soft iron, each particle of which will re-act, by its induced magnetism, upon the point of the magnet to which it adheres, and maintain in that point its primitive magnetic state.

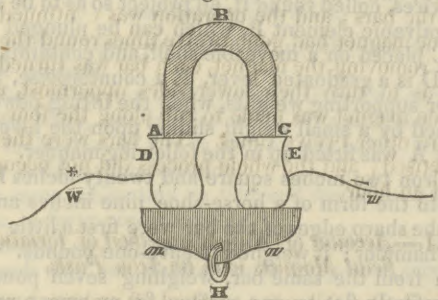
SECT. XIII.—*Account of the method of making Temporary Bar-Magnets of Soft Iron under the influence of Electric Currents.*

Electro-magnets.

In our history of ELECTRICITY we have given some account of the discoveries of M. Arago, Sir H. Davy, M. Savary, and others, relative to the communication of magnetism to steel by ordinary electricity. The subject will be resumed under the article VOLTAIC ELECTRICITY; but, without anticipating what properly belongs to that science, we shall give an account in this section of the method of making bar-magnets of soft iron by the influence of electric currents.

This process consists in winding spirally round a horse-shoe bar of iron ABC, a copper wire covered with silk thread. A galvanic current is then made to pass through the bar ABC by two wires W, *w*, communicating with two wooden vessels D, E containing mercury. When the voltaic apparatus consists of a single element, viz. one plate of zinc placed in a copper vessel, and having an area of five square feet, the magnet, when armed, as shown at *mn*, may suspend by the hook H 100 kilogrammes.

Fig. 73.



M. Moll[3] took a horse-shoe bar 0·22 of a metre high, and 0·025 thick, and rolled round it eighty-three times a copper wire covered with silk, and 0·003 of a metre in diameter. To each of the branches was adapted a counterweight of a pound weight, and projecting a little on both sides. The two extremities of the wire were made to communicate, by small vessels of wood filled with mercury, with two elements of a voltaic battery, composed of a bucket of copper, in which was plunged a plate of zinc, whose surface, in contact with the fluid, was eleven square feet. The moment the communication was made, the magnet supported twenty-five kilogrammes, and with some precautions thirty-eight. Another horse-shoe bar, weighing thirteen kilogrammes, 0·93 of a metre high, and fifty-five millimetres thick, lifted seventy-seven kilogrammes. When the direction of the current is changed, the poles of the magnet are instantly reversed; and when the current is stopped, the magnetism of the bar diminishes, though M. Moll found it capable of carrying twenty-five kilogrammes a quarter of an hour after the current ceased. M. Moll found that the magnetic intensity of the bar was not increased by increasing the number of the voltaic elements or plates; that a horse shoe of copper was not magnetised; and that a horse-shoe magnet was not rendered more magnetic by the electric current.

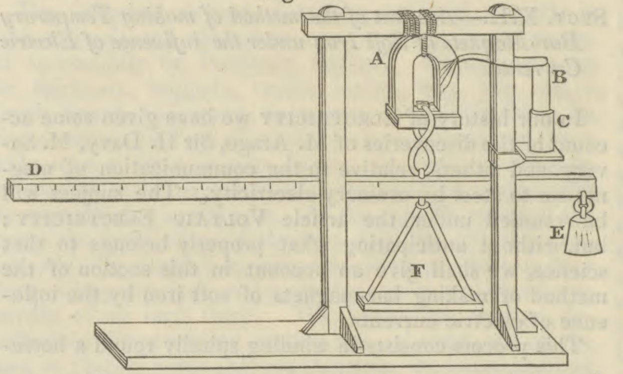
[3] *Ann. de Chim.* vol. l. p. 326.

Professor Henry.

Professor Henry of Albany Academy had obtained analogous results about the same time with Professor Moll. The apparatus which he used is shown in the annexed figure, which represents a strong rectangular wooden frame three feet nine inches high, and twenty inches wide. The magnet A is covered with linen, and the ends of the wires, coiled round it, all project so as to be soldered to the galvanic element B, which can be plunged into the vessel C placed on a moveable shelf, and containing dilute acid. D is a graduated lever, E a counterpoise, and F a scale for supporting weights, when the lifting power is not estimated by a small weight sliding upon the lever. The magnet A was fitted up in the following manner. "A bar of soft iron two inches square and twenty inches long was bent into the form of a horse-shoe nine inches and a half high; the sharp edges of the bar were first a little rounded with a hammer; it weighed twenty-one pounds. A piece of iron from the same bar, weighing seven pounds, was filed perfectly flat on one surface, for an armature or lifter; the extremities of the legs of the horse-shoe were also truly ground to the surface of the armature. Around this horse-shoe 540 feet of copper bell-wire were wound, in nine coils of sixty feet each. These coils were not continued around the whole length of the bar, but each strand of wire, according to the principle before mentioned, occupied about two inches, and was coiled several times backward and forward over itself; the several ends of the wires were left projecting, and all numbered, so that the first and the last end of each strand might be readily distinguished. In this manner was formed an experimental magnet on a large scale, with which several combinations of wire could be made by merely uniting the different projecting ends. Thus, if the second end of the first wire be soldered to the first end of the second wire, and so on through all the series, the whole will form a continued coil of one long wire. By soldering different ends, the whole may be formed into a double coil of half the length, or into a triple coil of one third the length," &c.[1]

Fig 74.



In making experiments with this magnet, a small single battery was used, consisting of two concentric copper cylinders, with zinc between them; the whole of the zinc surface in action, including both sides of the zinc, was two fifths of a square foot, and the quantity of dilute acid only half a pint. The following were the results:

Number of Wires soldered to the Battery in succession.	Weight lifted, in Pounds avoirdupois.
1. Each soldered to the battery in succession	7
2. One on each side of the arch	145
2. One from each end of legs	200
3. One from each end of legs, and the other from middle of arch	300
4. Two from each end	507
6. Wires attached	570
9. All the wires attached	650
9. A plate of zinc twelve inches long and six wide, and surrounded with copper, substituted for the preceding battery	750

When a pair of plates, exactly *one inch square*, was attached to the wires, the weight lifted was eighty-five pounds.

Professor Henry mentions that this magnet weighed twenty-one pounds, and lifted more than thirty-five times its own weight, whereas the largest natural magnet known, and in the possession of Mr Peale of Philadelphia, lifts three hundred and ten pounds, or about six times its own weight.

MM. Lipkens and Quetelet.

MM. Lipkens and Quetelet found that great effects will be produced by small voltaic surfaces, provided that the chemical action is energetic, and that the degree of magnetism depends more on the size of the iron shoe, than on the dimensions of the voltaic plates.[2]

Mr Watkins.

The horse-shoe iron magnets formed by electrical currents are only temporary, and it became interesting to discover the time of duration of the magnetism. Mr Francis Watkins made some interesting experiments on this subject.[3] He found that when the *armature* or *keeper* is *removed* from the two poles of the magnet, it instantly loses all its magnetism when the electric current is cut off; but that if the *armature* is kept upon the poles, the soft iron magnet will retain its magnetism for a great length of time. Mr Watkins made a horse-shoe bar with a piece of soft iron eighteen inches in length and one inch in diameter, and he rendered it magnetic by winding round it in a single helix twenty feet of copper wire one fifteenth of an inch thick. The ends of the copper helix being connected with a single pair of voltaic plates, the horse-shoe, when rendered magnetic by the current, supported 125 lbs. The voltaic action continuing, the weight was reduced to 56 lbs., and the voltaic plates removed; the weight was also carefully removed, so as not to displace the armature or keeper. The sustaining power of the horse-shoe was then tried every day, and at the end of ten days it sustained 56 lbs. as firmly as it did at first. Another horse-shoe bar charged with magnetism in November, was as powerful, and rather more so, in April, than it was at first. After a lapse of fifteen weeks it frequently supported 30 lbs. This soft iron magnet was tried at the Duke of Sussex's house on the 27th of April, *and, though nearly*

Methods of making Artificial Magnets.

six months had elapsed since it received the magnetic virtue, it supported 100 lbs.; but the instant that the *keeper* was separated from its poles, almost all the magnetism disappeared. When the keeper was again applied, there was not enough of magnetism even to support the keeper.

Mr Watkins made some interesting experiments on the lifting powers of soft iron magnets when plates of mica of different thickness were interposed between the poles and the keeper. The magnet was of the size and shape already stated, but Mr Watkins has not mentioned the successive thicknesses of the mica plates, nor does he state that they were of equal thickness. Had he mentioned the tints which each of them polarized, it would have been easy to compute their exact thicknesses. The following were his results:—

Number of Plates of Mica interposed.	Number of Pounds supported besides the Keeper.
1	49
2	40
3	26
4	17
5	13
6	8
7	4½
8	2½
9	2
10	1½

13	0½
14	The keeper only.
15	0

When a piece of common *writing paper* was placed between the poles and the keeper, 28 lbs. were supported by the magnet.

SECT. XIV.—*Account of M. Aimé's method of making Permanent Artificial Magnets.*

Aimé's Method.

This method, which has been recently published by M. Aimé,[1] is one equally simple and efficacious. It is founded on the facts described in the preceding section, and consists in holding a bar of red-hot steel with pincers between the two poles N, S of a horse-shoe magnet rendered magnetic by an electrical current. The horse-shoe and the included bar, which should exactly fit the space between the poles, are then plunged in cold water, and kept there for a little time, depending on the size of the real magnet, till the bar is thoroughly cold along its axis. In order to prevent the brass spiral wire that is curled round the horse-shoe bar from being wetted when the apparatus is under water, the extremities of the wire are enveloped in a piece of linen covered with mastic. The ends of the conducting wire should be soldered to the zinc and copper ends of the battery. M. Aimé employed a single wire for the spiral round the horse-shoe; but he observes that several may be united in a bundle, or a copper riband may be used covered with silk or varnish. In all the different trials that M. Aimé has made of this method, he has obtained satisfactory results.

SECT. XV.—*Account of the Experiments made by Coulomb and Kater, on the efficacy of the different methods of making Artificial Magnets.*

Coulomb's comparison of different methods.

Coulomb was the first person who examined experimentally the value of the different methods of making artificial magnets. The following is a brief abstract of his results.

Methods of making Artificial Magnets.

1. *Wires of tempered steel, twelve inches long and one twentieth of an inch in diameter.*

When rubbed at right angles on the pole of a single artificial magnet, it performed ten oscillations in seventy-four seconds.

When rubbed at right angles upon the poles of four united bar-magnets, or magnetised by the methods of Duhamel and Æpinus, it performed the same number of oscillations in the same time. Hence *small* steel wires attain their maximum degree of magnetism equally well by all the different methods.

2. *A plate of annealed steel twelve inches long, one third wide, and one forty-second of an inch thick.*

When rubbed at right angles on a single pole, it performed ten oscillations in seventy-seven seconds.

When rubbed on *two* united poles, ten oscillations in seventy-five seconds.

When rubbed on *ten* poles, ten oscillations in seventy-five seconds.

By the methods of Duhamel and Æpinus, ten oscillations in seventy-five seconds.

The effect of the different methods is now perceptible, the first being the worst.

3. *A plate of steel six and a half inches long, nine twenty-fifths wide, and one forty-second thick.*

When rubbed on two poles, ten oscillations in fifty-one seconds.

Upon five poles, ten oscillations in forty-nine seconds.

Upon eight and ten poles, ten oscillations in forty-seven and a half seconds.

By Duhamel's and Æpinus's methods, ten oscillations in forty-seven and a half seconds.

4. *A plate eight inches long, fourteen twenty-fifths wide, and one twenty-fifth thick.*

When rubbed upon *one* pole, ten oscillations in seventy-three seconds.

Upon *four* poles, ten oscillations in sixty-two seconds.

Upon *ten* poles, ten oscillations in fifty-nine seconds.

At an inclination of 15° or 20°, on *two* poles, ten oscillations in fifty-three seconds.

At the same inclination on *four* and *ten* poles, ten oscillations in forty-nine seconds.

By Duhamel and Æpinus's methods, with *one* or more bars on each side, ten oscillations in forty-nine seconds.

5. *Bar of steel sixteen inches long, six tenths wide, and one fifth thick.*

By magnetising it on Æpinus's method, with *two* moveable bars rubbing on its surface, it performed ten oscillations in a hundred and ten seconds, and was found to be saturated. By Duhamel's method, it required moveable bundles of four bars each.

6. *Bar of steel sixteen inches long, one inch broad, and nine twenty-fifths thick.*

When magnetised by Æpinus's method, with bundles of four, or even ten bars, it performed ten oscillations in a hundred and fifty-three seconds.

But by Duhamel's method, with even *ten* bars, it only performed ten oscillations in a hundred and sixty-two seconds.

Hence the magnetic force communicated by the first method was to that of the second as nine to eight.

Directive force of needles.

Captain Kater made a series of interesting experiments on the directive force of needles, produced by different

---

[1] *Ann. de Chimie*, vol. lvii. p. 442.

Description of Magnetical Instruments.

methods of magnetising them. The needles which he used were right-angled parallelograms, five inches long, the one seven tenths of an inch broad, and the other three and a half tenths. The broadest was made thinner till it had the same weight as the other, which was 142 grains. The following table contains the result of the experiments.

	Directive Force.	
	Small Needle.	Large Needle.
1. The magnets placed perpendicularly on the centre of the needle, and the needle rubbed from end to end on both sides..................	655	674
2. The same, but the magnets separated at top in the same way as at bottom..................................	595	580
3. The same as number one, but the distance of the lower ends of the magnets two and a half inches....	760	780
4. The magnets joined on the centre of the needle, and each moved towards the nearest pole, then lifted up and joined again, and so on....	993	1155
5. The magnets being joined on the centre of the needle, their lower ends were made to move to each pole, their upper ends remaining in contact..............................	1025	1150
6. By Duhamel's method, the magnets inclined 45° to the needle, and moved from the centre to the poles..	1070	1170
7. The same, but the inclination of the magnets 20°......................	1085	1195
8. The same, but the inclination only 2° or 3°................................	1160	1275
9. Magnets laid flat on the needle, and drawn from the centre to the end..	1158	1261
10. Same as number eight, but the separated ends of the magnets connected by an iron wire.............	1145	1261
11. Wire removed, and experiment number eight repeated..............	1260	1273
12. Needles hardened at a bright red, and then softened from the centre to within three fourths of an inch of their extremities, and magnetised as number eight............	1815	1665

Captain Kater next ascertained the effect of length on the directive power of needles. He cut two needles of equal weight out of the same plate of steel, the one being *five*, and the other *eight* inches long.

13. Magnetised to saturation as in number eight..........................	1193	2275
14. Hardened and tempered beyond the blue, from the middle to within an inch of the poles..................	1865	2277

Hence it follows, as Coulomb had ascertained, that the directive force of needles whose length exceeds five inches is probably as their lengths.[1]

CHAP. XI.—DESCRIPTION OF MAGNETICAL INSTRUMENTS.

Magnetical instruments.

The great importance and value of magnetical instruments, not only in the arts of navigation and surveying, but in the determination of the various and ever-changing phenomena of terrestrial megnetism, renders it necessary that we should enter with some detail into this branch of the subject. As a magnetic needle constitutes the principal, if not the essential part, of the greater number of magnetical instruments, we shall begin our observations with some details respecting the forms, description of steel, temper, and construction of magnetic needles.

SECT. I.—*On the best Form and Construction of Compass Needles.*

Form, &c. of compass needles.

The most valuable experiments on this subject are those made by M. Coulomb and Captain Kater. Those of Captain Kater are particularly important.

With regard to the material out of which the needle should be formed, Captain Kater found that needles of *shear steel* received a greater magnetic force than those of *blister steel* or *spur steel*, those of *cast iron* being much inferior to the others.

Coulomb's experiments.

The next object of inquiry was to ascertain the form of the needle which is best suited for receiving the greatest directive power. The forms which have been generally used are, the cylindric, the prismatic, that of a rhomb or a parallelogram, and that of a flat bar which tapers to its extremities like an arrow. According to the experiments of Coulomb, the form last mentioned, "*une lame taillée en flèche*," was the best, and was susceptible of a greater directive power than those which had the form of a parallelogram. He found that any expansion of the needles towards these poles was accompanied with a loss of power; and he drew the general conclusion, that in needles of the same form, their directive forces are proportional to their masses. Captain Kater likewise found that the directive force was little, if at all, influenced by the extent of its surface; but that it depended almost wholly on the mass of the needle when it was saturated with magnetism.

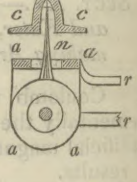
Captain Kater's experiments.

Captain Kater compared needles that had the form of a wide and a narrow rectangular parallelogram, and a small rhombus, a large rhombus, and a pierced rhombus, and he found that the form of the pierced rhombus is decidedly the best. A needle of this form (the sides of the rhombus are a little rounded in the figure), as made by Dollond, is shown in fig. 10, Plate CCCXXVI., the cross piece at the centre being made of brass or copper.

With regard to the best mode of hardening and tempering needles, Captain Kater found, that when a needle is considerably hardened throughout, its capacity for magnetism is diminished. He found that the needle was susceptible of the greatest directive power when it was first hardened uniformly at a red heat, and then softened from the middle to within an inch of its extremities, by using a degree of heat which is just capable of making the blue colour, which is thus produced, to disappear. Captain Kater likewise found that the polishing of the needle, previous to its being touched, had no advantage; and that an increase of pressure of the touching magnets on the needle was sometimes injurious, and never useful.

When the needle is magnetised, it has a cap *cc* fitted into the opening in its centre, seen in fig. 10, Plate CCCXXVI., and about one fourth of an inch in diameter. This hollow cap is executed with great care, and is generally made of agate (garnet is much better). The interior curved surface, particularly the summit of it, requires the best workmanship. This summit rests on the pivot *n*, the point of which is wrought to an angle of from about 15° to

Fig. 75.



---

[1] *Phil. Trans.* 1821, p. 104.

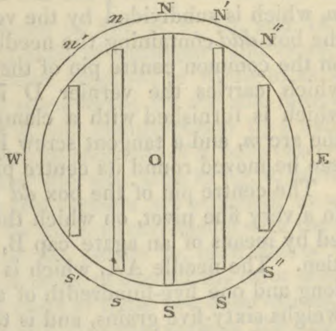
20°.[1] The use of the ring *a a* is to raise up the cap of the needle, and take it from the pivot when it is not in use. The rod or handle *r* of this ring is continued to the outside of the compass-box, where it can be put in motion, so as to disengage the needle from its pivot, or replace it at pleasure.

When a compass-needle is nicely balanced on a pivot, previous to its being magnetised, so as to traverse freely in a horizontal plane, it will no longer do so after it has been rendered magnetic. One of its ends will preponderate, in consequence of the tendency of the needle to dip, or place itself in a position parallel to the magnetic axis of the globe. In order to restore its equilibrium, therefore, it is necessary to add a small weight to one side of the needle, as shown in fig. 10 of Plate CCCXXVI. The weight requisite for this purpose will increase with the dip, so that it may be necessary to slide the weight farther from the centre in going towards the magnetic poles, and *vice versa*.

As the needle of ordinary compasses is generally placed upon a card on which the various points of the compass are marked, in stormy weather it is necessary to give weight to the card, to preserve it steady during irregular motions of the vessel. Various contrivances have been adopted to remedy this evil. The usual method is to load the card with sealing-wax. Some place pieces of paper, like vanes, on the lower side of the card, to act against the air, and check the vibrations; while others have proposed to make the needle move in oil or other liquid, with the same view. The consequence of these contrivances is, that while the weight of the card, or its resistance to motion, is increased, the directive power of the needle remains the same, so that in getting rid of one evil, another of greater magnitude is created. The mobility of the needle is diminished, and the steersman may mistake his course by trusting to the apparent steadiness of his compass. The simplest remedy for this evil is to use a heavier needle, with a greater directive power, or by combining several needles together.

This idea also has been proposed by Professor Barlow, who constructs the card as shown in the annexed figure, where NESW is the card, and NS, N′S′, N″S″, *ns*, *n′s′*, five parallel needles placed at equal distances. Mr Barlow has shown that the directive force of this combination of needles is nearly *four* times greater than that of a single needle; but as the weight and friction on the pivot is increased nearly in the same proportion, no other advantage is gained but the proposed one (particularly requisite in boat compasses) of making the cards steady by their additional weight, while the relative directive power remains the same.

Fig. 76.



Sect. II.—*Description of the Common and Azimuth Compass.*

The common compass, whether it is called the *mariner's compass* or the *land compass*, serves only to point out the direction of the magnetic meridian, while *azimuth* compasses enable us to determine the angular distances of objects from the magnetic meridian.

The common compass consists of a needle fixed to a circular card, containing upon its surface the thirty-two points of the compass. This card is balanced, as already described, upon a pivot fixed in the bottom of a circular box, and the top of the box is a plate of glass for protecting the needle from motions of the air. This compass-box, shown at AB, fig. 8, Plate CCCXXV., is suspended within a larger box PQ, upon two concentric brass circles or gimbals, the outer circles being fixed by horizontal pivots both to the inner circle, which carries the compass-box, and likewise to the outer box, the two axes upon which the gimbals move being at right angles to each other. The effect of this construction is, that the compass-box AB will retain a horizontal position during the motions of the vessel.

Description of Magnetical Instruments.

Azimuth compass.

The azimuth compass, shown in fig. 8, Plate CCCXXV. differs from the common compass principally in its being furnished with sights G, H, through which any object may be seen, and its angle with the magnetic meridian increased. For this purpose, the whole box is hung in detached gimbals CD, EF, which turn upon a stout vertical pin, seen above S′. In some instruments, the sights G, H may be turned down by a joint over the glass when the compass is not in use, as shown in fig. 7, Plate CCCXXV.; and in others they are connected by a brass bar, and may be taken from the compass when they are not wanted. In this compass, the card is divided on its rim into 360°; but the divisions are more frequently placed on a light metallic rim which it carries. The eye is applied to the sight H, which is a slip of brass containing a narrow slit. The other sight G, which is turned towards the object, contains an oblong aperture, along the axis or middle of which is stretched a fine horse hair or wire, which is made to coincide with or pass over the object or point whose angular distance or *azimuth* from the magnetic meridian is to be determined.

It is extremely difficult, when the ship is in motion, for the same person to take the bearing of the object and read off the angle; and various contrivances have been adopted to remedy this great defect. One of these is to have on one side of the compass-box a nut, which, when pressed by the finger, pushes a lever against the card, and stops its motion, so as to allow the angle to be read off at leisure; but a false reading is often obtained with this contrivance.

Sect. III.—*Account of Captain Kater's Azimuth Compass.*

Kater's azimuth compass.

This ingenious compass may be regarded as an universal instrument, capable of being advantageously used both at sea and on land. It is represented in detail in figures 7, 10, and 11, of Plate CCCXXV. In fig. 10, AB is a cylindric box made of brass, one inch deep, and covered with glass, and contains a card CD, five inches in diameter. The needle NS has an agate cap set in brass, and fixed in its centre. The needle is fixed to a circular piece of talc, on the circumference of which is laid a narrow ring of card, which is graduated to half degrees on its outer margin. On the inner side of the box there is fixed a standing piece of ivory, which just projects over the outer margin of the graduated circumference of the card, and an index-line is engraved on the ivory as a point of departure for reading off the divisions on the card. A brass sight-frame GH is fixed by a hinge at H, on the opposite side of the box. It has the form of a parallelogram, and is five inches long. A frame EF, two inches long, slides up and down upon GH, and contains the segment of a glass cylinder, whose radius is five inches. When the solar rays fall upon this cylindrical bar, they are collected into foci which form a line of light which is thrown upon the index-line of the

---

[1] Coulomb, *Mém. de l'Institut.* tom. iii. has shown that this is the best angle for pivots.

Description of Magnetical Instruments.

piece of ivory, and which may be seen at the same time as the divisions on the card. The frame GH, when folded down, as shown in fig. 7, acts upon a lever L, which raises the needle NS, and prevents it from traversing, by pressing it against the glass cover.

The sight-hole to which the eye applies itself is shown at P, figs. 10 and 11. It is an inch from its hinge to its summit, but may be raised higher by means of grooves, in which a branch below the joint covers it, as seen in the figure. The upright plane P has a slit S terminating below in a circular aperture, which receives a convex lens. To this is fixed a horizontal plane H, having a lens in its centre; and above this, inclined to it at an angle of 45°, is placed a mirror M, by means of which and the lenses, an eye looking through the lens below S sees magnified the divisions on the card, distinct vision being produced by sliding the sight upwards or downwards.

In order to take the sun's azimuth, raise the object-sight GH, and slide the cylindrical lens EF till its luminous line or focus falls upon the index. The eye-glass sight P is then to be moved up and down till it gives distinct vision of the index-line on the ivory. If the line of light is not narrow and well defined, incline the sight GH towards the compass till it is so, care being taken that the sight is perpendicular to the horizon, between the observer and the sun. When this is effected, incline the compass to the observer, so as to check the oscillations of the card, by bringing it in contact with the index and two pins fixed near it for the purpose. When the card is made steady by the repetition of this, taking care that the compass is inclined as much from the observer as will just free the card from the index, and that the line of light is bisected by the index-line, this lens will indicate on the card the azimuth of the sun required, which, when the correction on the card is applied to it, will give the true azimuth of the sun from the magnetic meridian; and by means of this element and the observed altitude, the variation of the needle may be obtained in the usual way.

In using this compass for surveying, the cylindrical lens is slid to the top EG, and the hair or wire GH is then seen; and when this hair is made to bisect any object seen by direct vision, we have only to read off the azimuth of that object as seen on the card viewed by reflection.

By turning back the reflecting sight P round its hinge, the line of light may be viewed on the index, and the angle read off by direct vision, a mode of observation which has its advantages.

Sect. IV.—*Account of the Variation Compass.*

Variation compass.

The very complete instrument for measuring, with the nicest accuracy, the variation of the needle, and ascertaining its diurnal changes, which we have represented in Plate CCCXXVI. fig. 2, was constructed in Paris, we believe by M. Gambey, and has been described by M. Pouillet. All the parts of it which are of metal are executed in copper. A table NN of white marble supports the pillars and case of the instrument. The columns C, D are those by which the needle is suspended, and E, F, G, H, those which support the microscopes M, M′. The box of the needle is shown at B, B′, and the needle itself AA′ is placed in the small copper ring *o p*, to which is fastened a wire or a number of silk threads without torsion, which suspend the needle, and which may be rolled round the small cylinder seen between *c* and *d*, and turned round by the milled head *e*. This wire is kept in the centre of the little graduated circle *cd*, by crossing at that centre a small triangular aperture. The wire is enclosed in a small cage of glass, which rises between the two columns C, D, in order that the air may neither be agitated, nor penetrate into the box. By turning the milled head *e*, the needle AA′ may be raised or depressed at pleasure. Two moveable panes of glass shut up the apertures A, A′ of the box, which are above the two ends of the needle. Upon each of the extremities of the needle there is firmly fixed a small plate of ivory *mn*, *m′n′*, bearing a very minutely divided scale, each of the divisions having the angular value of 15′ or 20′.

When the apparatus has been placed as nearly as possible in the plane of the magnetic meridian, and carefully levelled, we must see that the silk thread is without torsion; and by a few trials the microscopes M, M′ may be directed so as to see the zero or index of the ivory scales at the ends of the needle. It is then easy to observe the displacements which the needle experiences, either by counting the divisions which have passed under the wire of the microscope, or by following its motions by means of the screw by which the microscopes are moved. Small microscopes, one of which is shown at *a*, and moveable round the rods *b*, *f*, are used to read off the position and course of each microscope M, M′ along the bar which carries it, and which regulates its lateral motion.

The telescope T is used for counting more conveniently, and consequently more correctly, the oscillations of the needle, when we wish to employ it for measuring the magnetic intensity. It carries before its object-glass a mirror, which reflects the vertical rays along the axis of the telescope.

Sect. V.—*Description of Colonel Beaufoy's Variation Transit.*

Beaufoy's variation transit.

This instrument, which was employed by Colonel Beaufoy in the valuable series of magnetic observations which he made between the years 1813 and 1821, is represented in perspective in Plate CCCXXVI. fig. 4, where EF is a mahogany board, which forms the support of the instrument, resting on three screws G, H, I, by which it can be levelled. Above this is a flat plate of brass EE, fixed to the board by a centre pin, and resting upon three studs projecting from the board. It has a small horizontal motion round the centre pin, by means of the screw W and milled head X. The plate EE carries the graduated arc *m*, which is subdivided by the vernier D projecting from the box *ddd* containing the needle AA. This box moves on the common centre pin of the plate EE. In the plate which carries the vernier D is fixed the frame *aab*, which is furnished with a clamp-screw L to fasten it to the arc *m*, and a tangent screw K, by which the box *ddd* can be moved round its centre pin.

The centre pin of the box *dd* and plate EE terminates in a very fine pivot, on which the needle AA is suspended by means of an agate cap B, for diminishing the friction. The needle AA, which is a cylinder, is ten inches long and one five-hundredth of an inch in diameter. It weighs sixty-five grains, and is terminated by two conical points; and it is furnished with the usual lever, &c. for lifting it from the pivot of suspension and lowering it again. There are within the box *dd*, and beneath the ends AA of the needle, two segments of brass, which have the centre lines drawn upon them; and these lines are brought to the points of the needle when the observation is made, by observing the coincidence through the double microscope M, which can be removed to the opposite end of the box.

The transit telescope OP rests on two pillars NN, fixed on the brass plate EE, and having at their summits small boxes *f* for the reception of the Ys, in which the pivots of the conical axis Q of the telescope are supported. At the end of one of the pivots of this axis is fixed a small divided circle R, on an arm of which, provided with a level S, are placed the verniers for reading

Description of Magnetical Instruments.

off the divisions. The eye-piece *h* admits a dark glass for solar observation, and the wires of the eye-piece are adjusted by screws at *g*. There is also a detached level TV, whose feet *k*, *l* are placed in different directions upon the plate EE, for the purpose of levelling it. The use of the telescope is for finding the true meridian by means of the sun or stars, and the meridian should be indicated by fixed meridian marks.

When the instrument is properly levelled, and the telescope placed in the true meridian, the needle is allowed to settle, and the box *dd* is turned upon its centre till its mark comes near the point A of the needle. The clamp-screw L is then fixed to the arc *m*, and the screw K is turned till the coincidence of the index with the point of the needle is seen through the microscope M to be perfect. The vernier D will then show the exact angle of variation, or the declination of the needle from the true meridian.

Sect. VI.—*Account of Dollond's Variation Transit.*

Dollond's variation transit.

This instrument is shown in fig. 5 of Plate CCCXXVI. A brass pedestal CD, supported by three screws for adjusting it horizontally, forms the foundation of the four pillars which support the transit telescope AB, on the axis of which is fixed the graduated circle E, provided with all the usual contrivances for the accurate adjustment of the axis of the transit, and with microscopes for reading off the degrees. A cap or cover, seen separately at *a*, and containing a lens, is placed before the object-glass of the telescope, in order to convert it into a transit microscope, the focus of the lens being suited to the distance of the needle, seen between C and D, and the divisions of the graduated circle in the compass-box CD, the centre of the lens corresponding accurately with that of the object-glass. By this method the correct place of the divisions, as well as of the needle, may be readily ascertained, and the extreme deviation, as well as its diurnal changes, accurately determined. This instrument may also be used as a theodolite, and employed also for taking altitudes and equal altitudes.

Sect. VII.—*Description of Dollond's Diurnal Variation Instrument.*

Dollond's diurnal variation instrument.

This instrument is shown in figs. 8, 9, 10, and 11, of Plate CCCXXVI. It is made of mahogany and ivory, in order to avoid the attraction supposed to reside in all the metals. The needle *ns* is supported by the silk fibre *cbd* passing over a pulley at *b*, and counterpoised by a ball *d*. The two microscopes, seen on each side of *b*, have two cross wires, which, by means of the nut, seen in fig. 9, moving the frame to which the two verniers are attached, as well as the microscope, may be made to correspond with the index-lines on the ends of the needle *ns*, each end of the needle being observed, in order to correct the error arising from eccentricity. The mean of these two observations, as read off on the verniers, will give the angle of the diurnal variation. The needles used with the instrument are shown in figs. 10, 11; and there is also a piece of brass, of the same form and weight as the needles, in order to detect any twist in the suspending fibres of silk. This instrument might be used for measuring the magnetic intensity, by applying a contrivance for discharging the needle at the required angle. The diurnal part of this instrument was constructed for Captain Foster, who has published the observations which he made with it in the *Philosophical Transactions.*

Sect. VIII.—*Description of the Dipping Needle as constructed by Messrs Gilberts.*

Gilbert's dipping-needle.

After the dip of the needle was observed, and its changes discovered, instruments of various forms were contrived and used under the name of *aipping-needles*, for measuring the dip or inclination of the needle to the horizon. One of the most recent and complete of these instruments, as constructed by Messrs W. & T. Gilbert, is shown in Plate CCCXXV. fig. 9, in perspective. It consists of a brass plate CAB, supported by three screws A, B, C upon a flat board or stand. In the centre of this brass plate is another, ED, concentric with the former, and moveable round a centre pin like the moveable plate of a theodolite. This plate ED carries two levels at D for adjusting the plate horizontally. Four supports, shown at E and F, carry the circular box HGP, or principal case of the dipping needle NS. Two equal brass bars, one of which is seen at KL, are firmly fixed across the case in a horizontal direction. Other two brass pieces *m*, *n* are fixed by screws to the centre of the bars K, L, and carry two finely polished planes of agate, on which the axis of the needle NS rests, and upon which it turns freely. There is a contrivance inside the box G, and on the other side of K, L, not seen in the figure, by which the observer, by turning the milled head P, can lift, by means of Ys, the needle from the agate planes, or lower it upon them, at pleasure; the Ys being carefully adjusted, so as always to leave the axis of the needle on the same part of the agate planes, and in the centre of the divided circle. In this instrument the ends N, S of the needle are graduated so as to act as a vernier scale for subdividing the degrees of the divided circle into $6'$. A microscope is attached to the rim of the glass face, so as to be easily placed on any part of it, for the purpose of reading off the dip. In this instrument the length of the needle NS is six inches.

In order to obtain an accurate measure of the dip, several measures of it should be taken; *first*, with the face of the instrument to the east; *secondly*, with the face to the west; and the same observations repeated after the polarity of the needle has been inverted, or the north pole converted into a south pole, and the south into a north one. The mean of these four sets of observations will be the true dip required.

An account of Mitchell's dipping needle, as constructed by Nairne for the Board of Longitude, will be found in the *Phil. Trans.* for 1772, p. 476. The needles were a foot long, and the ends of the axes, which were made of gold alloyed with copper, rested on friction wheels four inches in diameter.

A complicated dipping-needle by Dr Lorimer, for determining the dip at sea, it described in the *Phil. Trans.*, 1775, p. 79.

The dipping-needle used by the Royal Society, and regarded as a model for instruments of this kind, is described by Mr Cavendish in the *Phil. Trans.* for 1776, p. 375. The axis of the needle rested on agate planes, and there was a contrivance, as in Gilbert's instrument above described, for raising and turning the needle upon the same part of the planes.

In one of M. Gambey's dipping-needles, executed at Paris, and intended to be used at St Petersburg, the axis, instead of being cylindrical, is a knife edge, as in delicate balances. This edge is placed exactly in the centre of gravity of the whole compound needles, and is so fixed, that when the needle dips 71° (as at St Petersburg), the edge rests perpendicularly on two agate plates. Such dipping needles, made for particular values of the dip, are admirably fitted for measuring minute variations of inclination, whether they be diurnal, menstrual, or annual.

Sect. IX.—*Account of Mr Scoresby's Magnetometer, for measuring the Dip of the Needle.*

Scoresby's magnetometer.

This ingenious instrument consists of a horizontal table, a leaf, or part of which, made of brass, may be set by a screw and pinion at any angle to the horizon; and this leaf contains near one of its edges two rings, through which we can pass a bar of soft unmagnetic iron, so that its length is perpendicular to the axis or line round which the brass leaf moves. On the same side of the leaf, and concentric with the above axis, is a graduated circle divided into 360°, so that when the bar of iron is put into the rings of the brass leaf, the bar coincides, in every position of the leaf, with a radius of the divided circle; and it is therefore easy to measure the angle which the bar makes with the horizon, whatever be the position of the leaf on which it rests. A compass is placed on the fixed leaf of the table, which by means of levels may be adjusted to a horizontal position.

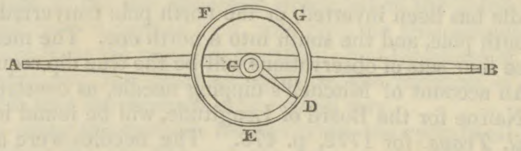
Now it has been ascertained by Mr Barlow, that when a bar of iron is in the magnetic equator, it loses all its power of affecting the needle of a compass placed near it. Mr Scoresby therefore elevates the brass leaf of the table, and consequently the bar of iron, till it ceases to act on the needle; and the complement of the inclination of the bar, as measured by the graduated circle, is the dip required. This method is of course not equal in accuracy to that described above, or to the methods of Meyer and Professor Lloyd, explained in subsequent sections. It may be used, however, most advantageously in obtaining an approximate measure of the dip when more delicate instruments cannot be procured. See the *Edinburgh Transactions*, vol. ix. p. 247; and the *Edinburgh Philosophical Journal*, vol. ix. p. 41.

SECT. X.—*Account of Daniel Bernoulli's Dipping-Needle.*

Bernoulli's dipping-needle.

If AB is a needle, C its axis, a light graduated circle DEFG is fixed upon it, so as to have its centre coincident with C, and a light index D is fitted to the axis C, so as to turn tightly upon it. Let the needle be magnetised previous to the putting on of the index D, and nicely balanced. The index will obviously destroy the equilibrium, and will always point perpendicularly to the horizon, if the needle has been properly balanced. As this degree of accuracy, however, cannot be expected, let the index D be set to different parts of the circle EFG, and let the inclination taken by the needle before it is magnetised be noted down, corresponding to the different positions of the index. When the index points to 50°, for example, let the inclination of the needle be 46°. If we now observe that the needle is still inclined 46°, when the index is at 50°, after it is magnetised, then 46° is the true magnetic dip at that place, as the magnetism which it has received does not alter the position which it assumes from its gravity alone.

Fig. 77.



As it is easy to obtain a rude estimate of the dip at any place, let the index D be set accordingly, and if the needle does not now show the estimated dip, the position of the index must be changed, and the inclination or dip of the needle again noted. Observe if this second position of the index, and the second measure of the dip, form a corresponding pair of numbers, such as have been written down. If they do we have got the true dip; but if they do not, another position of the index must be tried. If the coincidence of this new pair of numbers is greater or less than that of the former pair, we shall learn whether the position of the index is to be altered in the same direction as before, or in an opposite one.

Dr Robison made several observations with a dipping-needle of this construction, which was executed by a person totally unacquainted with the making of such instruments. He measured the dip with it at Cronstadt, at New York, and Scarborough, and the result never deviated more than $1\frac{1}{2}$° from that obtained by the present dipping-needles. He tried it also in a rough sea in Leith Roads, and he found it not inferior either in accuracy or despatch to the most elaborate instruments.

SECT. XI.—*Account of Mayer's Dipping-Needle, as constructed for Captain Sabine.*

The method of observing the dip employed by the celebrated Tobias Mayer,[1] consists in separating the centres of motion and of gravity of the needle, and in deducing the true dip from the apparent dip thus obtained.

The needle executed for Captain Sabine on this principle was a parallelopiped $11\frac{1}{2}$ inches long, $\frac{4}{10}$ths broad, $\frac{1}{20}$th of an inch thick. The ends were rounded, and a line drawn on the face of the needle through its centre to its extremities, for the purpose of an index. The needle turned upon a cylindrical axis of bell-metal, terminated by cylinders of the smallest diameter, that could support the needle without bending. These small cylindrical ends rested upon agate planes. The needle was raised from or lowered to its support by Ys, which insured that the same parts of the small cylinders rested on the agate planes in each observation.

A small steel screw was inserted in a female screw, tapped on the lower edge of the needle, in a direction perpendicular to the index line, and a small brass sphere was made to traverse on this screw, so that the centre of gravity of the needle, screw, and sphere, may be made to fall more or less below the axis of motion, and thus give the needle a momentum auxiliary to that of magnetism, in overcoming the inequalities of workmanship in the axis, or in the agate planes. Hence the position which the needle assumes, under these circumstances, is not that of the true dipping needle; but, by a simple formula, the true dip may be deduced from four observations, when conducted in the following manner:—

1. Place the needle in the magnetic meridian, and observe the angle which it makes with the vertical. Call this angle M.

2. Reverse the position of the axis on its supports, so that the edge of the needle, which was uppermost in the preceding observation, is now lowermost, and observe again the angle which the needle makes with the vertical, and call this *m*. Let the poles of the needle be now reversed by means of a powerful magnet, and when it is replaced, make the same observations which have been already described, and call the angles thus obtained N, *n*. Then calling the sum of the tangents of M and $m = A$; the difference of the same tangents $= a$; the sum of the tangents N, $n = B$, and their difference $= b$. Then the dip Δ may be obtained from the following formula:—

$$\text{cotan.}\ \Delta = \tfrac{1}{2}\left(\frac{A \times b}{a + b} + \frac{a \times B}{a + b}\right).$$

In order to insure the perfect horizontality of the agate planes, or of the axis of the needle which rests upon them, a spirit level attached to a circular brass plate, with adjustments to bring the level parallel to the plate, was placed upon the planes themselves. The errors of the level were shown by placing the plate in various positions, and the errors of the planes by turning the whole instrument on its horizontal centre.

---

[1] *Göttingen Transactions*, 1814.

Description of Magnetical Instruments.

If we observe the inclination of the dipping needle to the horizon in two different positions, so that the planes in which it moves are at right angles to one another, the true dip may be obtained from the formula:

$$\text{cotang.}\ {}^2\Delta = \text{cotang.}\ {}^2\text{I} + \text{cotang.}\ {}^2\text{I}'.$$

the inclination in the two rectangular azimuths being I, and I′. The dip may be thus very accurately obtained from the mean of a number of observations in different azimuths.

Sect. XII.—*Account of Professor Lloyd's method of observing the Dip and the Magnetic Intensity at the same time, and with the same Instrument.*

Professor Lloyd's method of observing the dip.

The ordinary dipping needle employed by Professor Lloyd, is supported on an axis which is supposed to pass accurately through its centre of gravity, and hence the position which it takes in the magnetic meridian is the direction of the magnetic force. If one of the arms of the needle, however, is loaded with a weight, the needle will assume a new position of equilibrium under the united influence of gravity and of terrestrial magnetism. By means of the inclination of the needle thus obtained, and the amount of the added weight, the dip of the needle, and the magnetic intensity, may be obtained by the following formulæ. Let μ, ν be the statical moments of two small weights attached in succession to the southern arm of the needle at fixed distances from its centre, and let ζ be the inclination obtained with the weight μ and θ that obtained with ν. Then

$$\mu \cos.\ \zeta = \varphi\, \sigma \sin.\ (\delta - \zeta),$$

$$\nu \cos.\ \theta = \varphi\, \sigma \sin,\ (\delta - \theta);$$

the dip being denoted by δ, and the magnetic intensity by φ, and σ being a constant depending on the distribution of magnetism in the needle itself. Hence from the inclinations ζ and θ observed in the usual manner, and the ratio of the moments μ and ν, the dip and the relative magnetic intensity will be obtained at the several places of observation.

The most advantageous way of applying the preceding method, Professor Lloyd considers to be this: He observes the position of the needle, *first*, when *unloaded;* and *secondly*, when loaded with a weight sufficient to bring it into a position nearly perpendicular to the line of the dip.

Now, if $\mu = o$, we shall have $\zeta = \delta$, or the inclination first observed becomes equal to the dip, when there is no weight acting with or against the directive force. This condition, however, is never accurately fulfilled, for, from the imperfect coincidence of the centre of gravity of the needle with the axis, the weight of the needle itself is sufficient to deflect it from the true line of the dip. We must, therefore, regard ζ as the approximate value of the dip, and compute the correction for reducing it to its exact value.

For this purpose put $\varrho = \frac{\mu}{\nu}$, and dividing the first of the above equations by the second, we have

$$\varrho \frac{\cos.\ \zeta}{\cos.\ \theta} = \frac{\sin.\ (\delta - \zeta)}{\sin.\ (\delta - \theta)}$$

Then if we make $\delta = \zeta + \epsilon$ the second term of the preceding equation becomes $\frac{\sin.\ \epsilon}{\sin.\ \zeta - \theta}$ *q.p.* since ϵ is a very small quantity, and we have

$$\sin.\ \epsilon = \varrho \frac{\cos.\ \zeta}{\cos.\ \theta} \sin.\ (\zeta - \theta).$$

Hence we may find the dip by means of these two equations, and we may deduce the correction for an imperfect balance of the needle from the two observed inclinations, without reversing the poles of the needle, as in the method of Tobias Mayer.

The value of the coefficient ϱ in the last equation is given in the following formula:

$$\varrho = \frac{\cos.\ \theta.\ \sin.\ (\delta - \zeta)}{\cos.\ \zeta \sin.\ (\delta - \theta)}.$$

The magnetic intensity at different stations may be obtained from the dip by the second equation.

The quantity σ being the statical amount of the free magnetism of the needle, or the *magnetic moment*, must vary with the temperature. If τ is the temperature of observation, τ' a certain standard temperature, and σ' the corresponding value of σ, then if we suppose the changes of σ to be proportional to those of τ, we have

$$\sigma = \sigma' (\text{I} - \alpha) (\tau - \tau')$$

α being a constant to be determined by observation, and which Professor Lloyd found to be 0.00016.

The quantity ν is the sum (or difference) of the moments of the weight of the needle, and of the added weight, and its value is

$$\nu = \nu' (1 - e \cos.\ 2\ \lambda)$$

where ν' is the value of ν corresponding to the latitude of 45°, λ the latitude of the place, and e a constant, whose value is 0.002588. Hence we obtain for the magnetic intensity

$$\varphi = \frac{\nu' \cos.\ \theta}{\sigma' \sin.\ (\delta - \theta)} + \frac{1 - e \cos.\ 2\ \lambda}{1 - \alpha (\tau - \tau')}$$

an expression peculiarly adapted for logarithmic computation. See *Memoirs of the Royal Irish Academy* 1835.

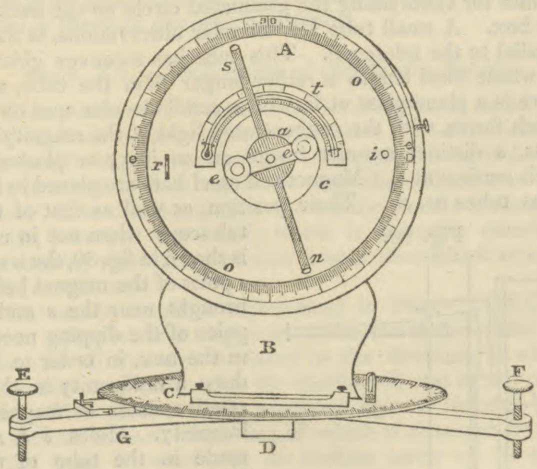
Sect. XIII.—*Description of Mr Fox's Dipping Needle Deflector, for measuring the Variation and Dip of the Needle, and the Magnetic Intensity.*

Mr Fox's Deflector.

This ingenious instrument, for ascertaining the variation, dip, and intensity of terrestrial magnetism, has been pretty extensively used by Mr Fox in different parts of the united kingdom. The results have been published both in a table and in a chart in an extract from the Report of the Royal Cornwall Polytechnic Society for 1835.

The deflector is shewn in the annexed figures, where A is a cylindrical box of brass fixed vertically in the stem B and horizontal plate C, all of which can be turned round on their common axis D, ground into the centre of a tripod, two of whose legs are shewn at E and F. The graduated circle in C is subdivided by a vernier and tangent screw G, levels being placed at right angles to each other for adjustment. The needle *ns*, with a small grooved wheel *a* fixed

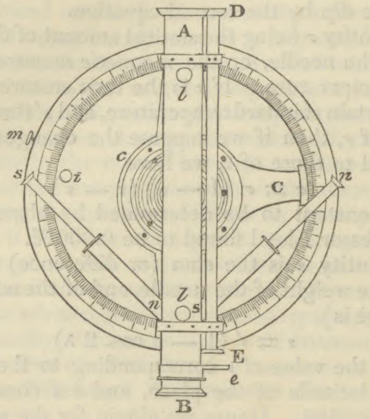
Fig. 78.



Description of Magnetical Instruments.

on its axis, is supported by the concentric disc *c*, and a bracket *e* attached to the disc, the axis of the needle moving in jewelled holes. The disc *c* is accurately fixed into the back of the box, and may be turned round with the bracket on its axis by means of knobs on its back, shewn in the annexed figure. By this contrivance the bracket may be moved round to any convenient position, so as not to interfere with the dip of the needle in any latitude.

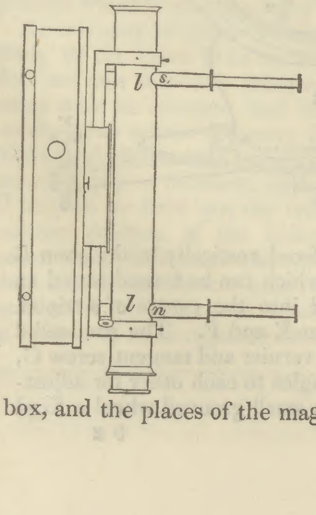
Fig. 79.



The socket *v*, fixed to a brass spring, when pressed forward by the screw *m*, is intended to confine the ends of the needle when not in use. There are two parallel graduated rings, one of which is a little within the outer surface of the dipping needle, as shewn at *oo*, fig. 78.; the other ring, supposed to be removed in the figure, is immediately under the glass, its object being to direct the sight, and enable the observer to subdivide the degrees on the inner circle. A thermometer is shewn at *t*. The back of the dipping needle box is shewn in fig. 79.; the back of the moveable central disc is grooved, and a brass rod is drawn over the grooved surface in order to make the needle vibrate.

A telescope AB, having cross wires, is capable of being moved in a vertical plane in any direction, by means of a concentric ring *c*, grooved into another concentric ring attached to the back of the instrument, and furnished with a flanch. An arm C, at right angles to the telescope, has a vernier for subdividing the graduated circle on the back of the box. A small tube DE for solar observations, is fixed parallel to the telescope. This tube has a convex glass at D, whose focal length is rather longer than the tube, and there is a plane glass at E, with a small circular spot on it, which forms, with the concentrated light of the magnifying glass, a distinct annular image on an ivory or plaster of Paris surface at *e*. Magnetised steel bars are placed in the brass tubes *ns*, *sn*. Their position, as well as that of the telescope, when not in use, is shewn in fig. 80, the *n* and *s* poles of the magnet being brought near the *s* and *n* poles of the dipping needle in the box, in order to induce a uniformity in their relative states of magnetic intensity. Holes *l l* are made in the tube of the telescope, to allow the magnets to be passed through it, and screwed into the arms which hold the telescope. This is shewn at *n* and *s* fig. 79, which represents a side view of the box, and the places of the magnet when employed for ascertaining the intensity. Screws for fixing the ring and glass cover, over the face of the instrument, are shewn at *a a*.

Fig. 80.



Description of Magnetical Instruments.

Fig. 81.

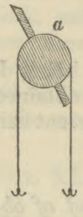


Fig. 81. represents a grooved wheel fixed in the axis of the needle *a*, with a fine silk thread, having hooks at each end, passing over the wheel in the grooves.

The following rules for using the instrument are given by Mr Fox:—

To observe the Magnetic Variation.—Ascertain the true meridian by any of the usual methods; the small tube being used for solar observations, and the telescope for observations at night. Note the angle cut by the nonius on the circular plate C. If the plate be turned round 90° from that point, the face of the instrument, or rather the plane in which the needle moves, being parallel to that of the tubes, will be at right angles to the plane of the true meridian. The deflecting tubes *n s* having been removed from the back, turn the instrument round *gradually*, so that the needle may become *perfectly vertical* after vibration; friction having been employed several times at the back of the central disc. Fig. 79.

The face of the instrument will then be at right angles to the plane of the magnetic meridian; and the angle described on the circular plate will give the variation from the true meridian. The face of the instrument, however, should always be turned round to the opposite quarter, till the needle again becomes vertical, which will either confirm or correct the preceding experiment, by taking half the difference between the two observations.

To ascertain the Dip.—The face of the instrument having been made to coincide with the *plane* of the magnetic meridian, suppose it to be at first turned toward the east; note the exact dip at *both* ends of the needle after vibration, as before described; (this precaution should, in every case, be carefully attended to, and repeated several times); then turn the face of it toward the west, placing it in the same plane, and observe and note as before; the mean of these observations will give the dip.

To correct the observed Dip.—The instrument being still in the magnetic plane, and fixed in that position by means of the lever or clamp, connected with the nonius, screw on one of the deflectors *n s* at right angles to the tube, as shewn in fig. 80, so as to repel or deflect the end of the needle which is nearest to it; then, if the observed dip was 69°45′, move the deflector a certain number of degrees from 69°45′, as shewn by the nonius *c*; say 50° to the right of the dip, when the needle will be repelled in the opposite direction; suppose the mean angle at *both* poles of the needle, after frequent vibrations, to be . . . 54°33′
then move the tube 50° to the left of the dip, when the needle will be repelled in the contrary direction: suppose it to stand at . . 84°47′

Mean, . 69°40′

If the face of the instrument, whilst making these observations, should be towards the east; turn it round towards the west, adjusting it in the same plane, and repeat the observation; if the mean result should be . . 69°46
the mean or corrected dip will be . . . 69°43

Similar observations may be multiplied at pleasure, by varying the angles of the deflector from the observed dip; and by thus taking the mean of many observations, the true dip may be obtained with a great degree of precision.

To find the relative Intensity of the Terrestrial Magnetism. The instrument being still in the plane of the magnetic meridian, screw the deflectors (or one of them) into the arms at the back of the instrument, as shewn in fig. 79, and cause the latter to coincide with the direction of the dip, when the needle will be repelled from it; mark the angle to which the needle points at both ends (after repeated vibrations as before described), then cause the needle to swing back to the other side of the dip (one of the deflectors being temporarily removed for this purpose), and note its place as before: half the sum of the angles to which the needle is thus deflected (or rather of their sines) will represent the relative force of the terrestrial magnetism, at different places, on a needle thus circumstanced. It is desirable that the observations should be made with the face of the instrument turned towards the east as well as towards the west; and likewise only one deflector may be used as well as both of them, in order to vary and multiply the observations for the purpose of correction.

If the angle of deflection at a second place of observations should be greater or less than at the first, the force of the earth's magnetism will be inferior or superior to the latter, as represented by the different angles.

The amount of any such difference may, when required, be represented by weights:—For this purpose, the glass which protects the face of the instrument should be removed, and the silk thread placed on the grooved wheel, as shewn in fig. 81. The minute weights required to be suspended to one of the hooks, in order to bring the needle to some given angle from the actual dip, will indicate the relative magnetic intensity at different stations. Suppose, for example, that at a given place, the observed dip is 70°, and that at a second place, in a lower latitude, it is 45°; adjust the deflectors as before described, so as to coincide with the dip of the needle at the place of observation, whatever it may be. Assume that the needle is repelled 70° from the dip of 70° at the first station, and 80° from the dip of 45° at the second station; it will shew that the terrestrial magnetic intensity is greater at the former than at the latter. The weights required to be suspended to one of the hooks, in order to bring the needle to its original position of 70° from the dip (if that be taken as the standard) will indicate the difference of intensity. Thus, for instance, if five-tenths of a grain be required to bring the needle from the angular distance of 80° to that of 70° from the dip at the second station; this weight will indicate the *difference* of the magnetic intensity of the earth at the *two* stations, acting on the needle in question, when at an angle of 70° from the natural dip.

The ratio of this difference to the whole force of the terrestrial magnetism so acting, may be ascertained by moving the deflectors to the angle of 70° from the dip (because the needle is assumed to have been deflected to this angle at the first station), the needle will then be repelled to the opposite side of the dip, and the weight required to counteract the deflection sufficiently, to bring it back to the dip, will represent the whole influence of the earth's magnetism, at the first station on the needle, whilst at the angle of 70° from the dip. This will be evident, when it is considered that the angle between the needle and deflectors is in both instances the same; it being coerced, contrary to the repelling force of the deflectors, in one case by the earth's magnetism, and in the other by the weights, to the *dip or line of quiescence*. The earth's magnetic force acting on the needle so deflected, and the weights will therefore be equal to each other. If 3.34 grains be the weights required, and five-tenths of a grain equal to the difference between the two stations, the terrestrial magnetic intensity will be in the ratio of 3.34 — .5 = 2.84, at the second station, to 3.34 at the first station.

From the observations which have been already made with the dipping needle deflector, furnished with a needle less than six inches long, there is good reason to believe that it will clearly indicate a difference of intensity at places situated at less than one-half a degree of a latitude from each other.

Observations on the magnetic intensity and dip may likewise be made *without the deflectors*, by means of the weights only, suspended from the silk thread, shewn in fig. 81. This method is too obvious to require a minute description, the weights in this case being used to produce deflection from the dip at any place, instead of the magnetic deflectors: the weights required to cause a given amount of deflection being taken as the relative measure of the magnetic intensity at the place of observation. Thus, in the case before supposed, 3.34 grains would produce a mean deflection of 70° from the dip at the first station, and only 2.84 grains would do so at the second station.

Description of Magnetical Instruments.

Sect. XIV.—*Account of Lebaillif's Sideroscope.*

Lebaillif's sideroscope.

The object of this instrument, proposed by M. Lebaillif, is to detect minute degrees of magnetism by means of a very delicate combination of small magnetic needles. This apparatus, which he calls a *Sideroscope*, is shewn in Plate CCCXXVI. fig. 3, where ABCD represents the body of the instrument. The other parts consist of three sewing needles magnetised to saturation, and a tube of straw twelve or fifteen inches long. One of these needles, *a b*, is slid into the tube *m h*, and the others *a′ b′*, *a″ b″*, are placed across the straw, so that their dissimilar poles correspond. The straw thus fitted up is placed upon a small stirrup of paper, which is suspended by a silk fibre fixed at the top C, of the vertical tube of glass or wood C D. The portion *m h* of the tube of straw is the longest, and it is beneath its extremity *m* that there is placed on the bottom of the cage or box A B, an arch *r r r*, divided into degrees and half degrees. The portion *m c* has no directive force, as the action of the earth is neutralized in the two opposed needles *a′ b′*, *a″ b″*. But the portion *m h* has a directive force depending on the magnetism of the needle *a b*, on its length, and on its distance from the point of suspension. The cage has a small sliding door, *t p*, which shuts up the apparatus; and when an experiment is made, the aperture at *t* is brought opposite the extremity *a* of the needle.

Plate CCCXXVI. fig. 3.

M. Lebaillif has proved, that almost all bodies exercise some action on the needle, and that *antimony* and *bismuth* always exert upon it a repulsive force. M. Pouillet, from whose work we have taken this description of the instrument, is of opinion that the movement of the needle may be often owing to atoms of iron; and that we must not take it for granted that, in these phénomena, the magnetic force is the only one which is acting.

Sect. XV.—*Description of the Astatic Needle.*

Astatic needle.

This instrument, described by M. Pouillet, is called the Astatic Needle, because it is withdrawn from the action of the earth's magnetism, and has no longer the statical position in which it is in equilibrio with the influence of this force. The construction of the astatic needle is founded on the principle that a body which is moveable round an axis cannot receive any motion from a force which acts parallel to this axis.

Plate CCCXXVI. fig. 1.

The astatic needle is represented in Plate CCCXXVI, fig. 1, where *n s* is a magnetic needle, moveable round the axis *a b*. If this axis is placed in the direction in which terrestrial magnetism acts, the needle will rest in any position. This effect is easily produced by two motions perpendicular to each other, one of which is obtained by the milled head S′, which, by an endless screw on its axis, works in the teeth of the wheel C, and the other by the milled head S′ and the wheel D. The graduated circle AB shewing the positions of the needle.

Pouillet's astatic needles.

Another contrivance for an astatic needle is shewn in the annexed figure (82), where two needles AB, A′B′, perfectly alike in their form and magnetic intensity, are turned in opposite directions, and placed upon the same axis perpendicular to their length.

Description of Magnetical Instruments.

A more perfect compensation in the action of two needles, is shewn in fig. 83, where AB AB are the two needles, the one horizontal and the other inclined to the horizon. It is obvious that the directive force of the latter will augment with its inclination, and it is therefore easy to make the directive forces of each perfectly equal and opposite, by varying the inclination of the uppermost one. These two contrivances we owe to M. Pouillet.

Fig. 82.

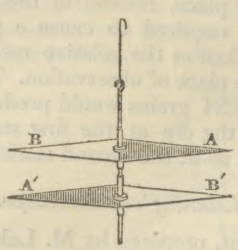

Fig. 83.

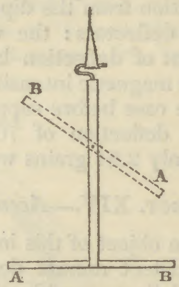

A magnetic needle may also be rendered astatic by neutralizing the action of the earth, by means of an equal and opposite magnetic action. For this purpose we have only to place a powerful bar magnet at a considerable distance from the needle, so that it may act upon it as powerfully as the earth does. It should be placed in the magnetic meridian, parallel to the direction which the needle takes when it is in equilibrio, the pole of the bar which repels that of the needle being placed nearest it. When the bar is placed near the needle, it will cause it to wheel round, in consequence of its action exceeding that of the earth. At a very great distance, on the contrary, the earth's action will predominate, and draw the needle into the magnetic meridian; but an intermediate distance will be found in which the two actions exactly balance or compensate each other, and render the needle astatic.[1]

SECT. XVI.—*Account of Barlow's Correcting Plate or Magnetic Compensator for neutralizing the effect of local attraction on the Ship's Compass.*

Barlow's correcting plate.

As every ship contains large fixed masses of iron, beside moveable iron guns, anchors, cables, and iron utensils of various kinds, it is obvious, from the principles and experiments already detailed (see Chapter V, &c.), that these masses, rendered temporarily magnetic by the action of the earth, must produce derangements in the magnetic needles of the compasses on board. These derangements amount sometimes to 15° or 20°, and have exposed navigators to the most imminent perils. Mr Wales, the astronomer to Captain Cook's expedition of discovery, first discovered the fact that such a deviation existed, but he does not seem to have suspected its cause. Mr Downie, master of his Majesty's ship Glory, was the first person who pointed out the true origin of the deviation. "I am convinced," says he, "that the quantity and vicinity of iron in most ships have an effect in attracting the needle; for it is found by experience that the needle will not always point in the same direction, when placed in different parts of the ship. Also it is rarely found that two ships, steering in the same course by their respective compasses, will go exactly parallel to each other, yet these compasses, when compared on board the same ship, will agree exactly."[2]

Description of Magnetical Instruments.

In his survey of the coast of New Holland, in 1801 and 1802, Captain Flinders observed great differences in the direction of the needle, which arose only from changes in the direction of the ship's head, the direction being westerly when the ship's head was to the east, and *vice versa*. Hence he concludes, that the attractive powers of the different bodies in the ship which are capable of affecting the compass are collected into something like a focal point or centre of gravity, and that this point is nearly in the centre of the ship, where the shot are deposited, for here the greatest quantity of iron is collected together."[3] He likewise supposes that this magnetic centre is of the same name as the pole of the hemisphere where the ship is, and consequently, that in New South Wales the south end of the needle would be attracted by it, and the north end repelled; and from this hypothesis he concludes that the phenomena must be exactly the reverse in the northern hemisphere.

The Admiralty ordered a course of experiments to be made on this important subject, but though they established the truth of Captain Flinder's views, the subject was not farther prosecuted. The public attention, however, was again called to it by Mr Bain, who, in an excellent treatise on the variation of the compass, pointed out the fatal consequences which might result from this great source of uncertainty in the indications of the needle. The observations of Captains Ross, Parry, and Sabine threw additional light upon the subject; but it is to Professor Barlow alone that we owe a series of brilliant experiments, which terminated in his invention of the neutralizing plate, for correcting in a perfect manner this source of error in the compass.

In order to give an idea of the magnitude of this error, Professor Barlow has published the following table of deviations actually observed:—

Ship.	Place.	Observers.	Deviation in the compass.
Conway	Portsmouth	Captain Hill	4° 32′
Leven	North fleet	Captain Owen	6 7
Barracouta	Do.	Captain Cuttfield	14 30
Hecla	Do.	Captain Parry	7 27
Fury	Do.	Captain Hoppner	6 22
Griper	Nore	Captain Clavering	13 36
Adventurer	Plymouth	Captain King	7 48
Gloucester	Channel	Captain Stuart	9 30

The instrument employed by Professor Barlow is shewn in the annexed figures, where T is a rod of copper an inch and a half in diameter, and FF′ two plates of iron about twelve or thirteen inches in diameter, and of such a thickness that a square foot of it will weigh about 3 lbs. avoirdupois. These plates are separated by a circular sheet of card, and pressed against each other at their centre by a screw on the end of the rod T, and at their margins by three small screws of iron. The compass C is placed on the tip of a wooden box B, and the corrector T is placed in one of the holes in the side of the box.

Theories of Magnetism.

The adjustment of the plate is made when the ship is lying in a calm bay near the shore. An observer with a needle and theodolite is placed at some distance from the shore, from which he can perceive the ship while it is turning its head in different directions. The compass on board the ship is under the management of another observer with the same apparatus. At a signal given the observer determines the angle which his own needle makes with the axis of the telescopes (one being directed to the other), which is called the central line. But as the needle on shore experiences no disturbing action, it is evident that if the needle on ship-board also experience none, the two needles will be parallel, and will form the same angle with the central line. Hence the difference between these two angles when they are not the same is that which is produced by the magnetic action of the iron in the vessel from its compass needle at the instant of observation. Let the vessel be now made to turn round completely, and let a new observation be made at every azimuth of ten or twelve degrees, we shall then have the value of the deviation produced in all positions of the ship's head upon the compass needle. When this is done, the observer on shore takes away his compass and replaces it with that of the ship, which he sets on the wooden cage shewn in fig. 84, having different holes for receiving the axis T of the plate FF′. As the box B is turned round its axis it carries along with it the compensator FF′, which will affect the needle of the compass C differently in different azimuths, and by a few trials it may be adjusted by means of the holes of its axis T to produce the very same deviations in the compass as was produced upon it when in the ship by the action of its iron. When it is done the position of the centres of the plate FF′ with regard to the needle is completely marked, and when it is taken on board the ship and placed in its proper position, the compensator is adjusted on the stand which carries the compass, as shewn in fig. 85, so as to have exactly the same relative position as it had in the box B.

Now since the compensator produces the same effect as the iron on shipboard does, the deviation will be *doubled* in place of being corrected; but this furnishes the means of making the correction. If the variation is found to be 36° W. by the compass *without the compensator*, and afterwards 40° with the compensator, the difference $40° - 36° = 4°$ shews that the compensator augments the variation 4°, and the iron on board the vessel as much. Hence the true variation will be $36° - 4 = 32°$, or $40 - 4 - 4 = 32°$. If the observations with the compensator had given a less result than without it, this would have shewn that the action of the iron had diminished the declination, and the difference of the two observations must have been added to the first to have the true declination.

CHAP. XII.—THEORIES OF MAGNETISM.

Theories of Magnetism.

The phenomena of magnetism, like those of every other branch of physics, have afforded the groundwork of many absurd and wild theories. The hypotheses of Descartes and Euler, which created in the interior of magnetic bodies canals and valves to admit or obstruct the subtle matter, to the agency of which they ascribed the attractive or directive power of magnets, are too ridiculous to deserve any notice in the present state of the science.

Theory of Æpinus.

M. Æpinus of St Petersburg was the first philosopher who discovered a rational hypothesis, which explained nearly all the phenomena of magnetism. This hypothesis of one fluid, however, of which we have already given a short account in our history of the science, was found insufficient for explaining the phenomena which are exhibited in the division and fracture of magnets, and that it was susceptible of a correction, which consisted in considering a magnet as composed of small particles of iron, each of which has individually the properties of a separate magnet, yet it did not afford a complete explanation of all the magnetic phenomena.

Theory of Wilcke, &c.

The hypothesis of two fluids, which was first proposed by Wilcke and Brugmann, was established by M. Coulomb and has recently been perfected by the masterly investigations of M. Poisson, who has not only constructed mathematical formulæ which enable us to calculate all the minutest details of the phenomena, but has enabled us to comprehend physically how all the phenomena have been produced. The general equations at which he has arrived have not yet, in every case, been resolved; but the particular conditions under which the integrations are possible have already, as we have stated, exhibited the most happy coincidence with experiment.

The hypothesis of two fluids supposes that they reside in each particle of iron; that they are neutral, and inert when combined as in soft iron; and that, when they are decomposed, the particles of the *austral* fluid attract those of the *boreal* fluid, and *vice versa* while they each repel one another.

In order to account for the phenomena of the division and fracture of magnets, it is necessary to suppose, that when the united fluids are decomposed, the fluids undergo displacement only to an insensible distance. The minute portions of a magnetic body within which the motions and displacements resulting from decomposition take place, or in which magnetism exists, are called the *magnetic elements* of that body, and the small intermediate spaces where magnetism is not found, the *non-magnetic* elements. It is impossible to determine whether the *magnetic elements* are the intervals which separate the ultimate atoms of material bodies, or if they are the atoms themselves; nor can we ascertain whether they are the intervals between an aggregate number of atoms, or of a secondary molecule, or the aggregate members themselves. The theory regards the sum of the magnetic elements, and of the non-magnetic elements as forming the apparent volume of a body. The ratio of these two sums may change with the nature and temperature of the body; and these changes exercise a powerful influence over the distribution and intensity of magnetism.

The quantity of each fluid in every magnetic element is unlimited in reference to our powers of separating them, as the united fluids can never be completely decomposed. The force which prevents this decomposition, and also the recombination of the fluids, is called the *coercive force*, and, like that of friction, it cannot be completely overcome. In soft iron, this coercive force is extremely feeble. In the natural loadstone, and in steel, it is very powerful, varying in intensity in different kinds of this metal.

One of the most important consequences of the theory of Poisson is, that a magnetic needle whose size is so small that it exerts no sensible action on an iron sphere within which it is placed, will intercept the magnetic influence of the earth, and of all magnetic bodies without the sphere; and, in like manner, such a sphere will intercept the action of a magnet within it on all bodies without it. Another interesting consequence of the theory is, that in a hollow iron sphere, magnetised by the influence of the earth, or of any magnetic force, the origin of which is at such a great distance that it may be considered as acting in parallel lines, although the magnetism is not confined to the surface of the sphere, and though its intensity may be determined for any particular point of the solid mass of the shell, yet it is determined only by the radius of the external surface, and the co-ordinates of the point upon which the forces act. When this point is very remote from the centre of the sphere compared with its diameter, each of the three forces is nearly in the direct ratio of the cube of the radius, and in the inverse one of the cube of the distance.

M. Poisson has likewise applied his powerful mind to the explanation of the singular phenomena of magnetism produced by rotation. To the suppositions which his theory makes in order to explain the phenomena of magnetism induced by influence, he adds another, namely, that all bodies exert upon the *boreal* and *austral* fluids a species of action analogous to the resistance of media, which action has the effect of retarding the motion of the two fluids in the interior of the magnetic elements; and he conceives that it is this species of resistance, and not the coercive force, which has an influence over the magnetic phenomena of revolving bodies. Hence, if we bring a magnet near any body on which the coercive force is insensible, and in which the magnetic elements are in any proportion, the decomposition of the neutral fluid will begin immediately, and will continue till the action of the free fluid is in equilibrio with the external force, which will certainly take place if this force is constant in magnitude and direction. But if it varies continually, or if the loadstone changes its position, the two fluids, in place of arriving at a permanent state will move in each element with velocities dependent, other things being equal, on the resistance which the substance of the body opposes to them.

It is needless to enter into any further details respecting this very ingenious theory, as the recent discoveries of Mr Faraday respecting electro-magnetic induction have enabled him to give a most satisfactory explanation of the diversified phenomena of magnetism in motion.
